PART VI Using Information Systems and Technology to Support Individual and Group Tasks

PART VII Managing and Securing the IT Infrastructure and Systems

Preface to the *Computing Handbook Set*

The purpose of the *Computing Handbook Set* is to provide a single, comprehensive reference for specialists in computer science, information systems, information technology, software engineering, and other fields who wish to broaden or deepen their understanding in a particular subfield of the computing discipline. Our goal is to provide up-to-date information on a wide range of topics in a form that is accessible to students, faculty, and professionals.

The discipline of computing has developed rapidly since CRC Press published the second edition of the *Computer Science Handbook* in 2004 (Tucker, 2004). Indeed, it has developed so much that this third edition requires repartitioning and expanding the topic coverage into a two-volume set.

The need for two volumes recognizes not only the dramatic growth of computing as a discipline but also the relatively new delineation of computing as a family of five separate disciplines, as described by their professional societies—The Association for Computing Machinery (ACM), The IEEE Computer Society (IEEE-CS), and The Association for Information Systems (AIS) (Shackelford et al., 2005).

These separate disciplines are known today as computer engineering, computer science, information systems, information technology, and software engineering. These names more or less fully encompass the variety of undergraduate and graduate degree programs that have evolved around the world. The document "Computing curricula 2005: The overview report" describes computing this way (Shackelford et al., 2005, p. 9):

> In a general way, we can define computing to mean any goal-oriented activity requiring, benefiting from, or creating computers. Thus, computing includes designing and building hardware and software systems for a wide range of purposes; processing, structuring, and managing various kinds of information; doing scientific studies using computers; making computer systems behave intelligently; creating and using communications and entertainment media; finding and gathering information relevant to any particular purpose, and so on.

To add much flesh to the bones of this very broad definition, this handbook set describes in some depth what goes on in research laboratories, educational institutions, and public and private organizations to advance the effective development and utilization of computers and computing in today's world. The two volumes in this set cover four of the five disciplines in the following way:*

1. Volume I: Computer Science and Software Engineering
2. Volume II: Information Systems and Information Technology

* This handbook set does not currently cover *computer engineering*, though we hope such coverage can be developed and added to the set in the near future.

This set is not designed to be an easy read, as would be gained by browsing a collection of encyclopedia entries on computing and its various subtopics. On the contrary, it provides deep insights into the subject matter through research-level survey articles. Readers who will benefit most from these articles may be undergraduate or graduate students in computing or a related discipline, researchers in one area of computing aiming to expand their knowledge of another area, or other professionals interested in understanding the principles and practices that drive computing education, research, and development in the twenty-first century.

This set is designed as a professional reference that serves the interests of readers who wish to explore the subject matter by moving directly to a particular part and chapter of the appropriate volume. The chapters are organized with minimal interdependence, so that they can be read in any order. To facilitate rapid inquiry, each volume also contains a table of contents and a subject index, thus providing access to specific topics at various levels of detail.

Preface to Volume II: Information Systems and Information Technology

We are delighted to introduce this new volume of the *Computing Handbook Set* on information systems (IS) and information technology (IT). Both of these disciplines focus on computing in a context (such as an organization) that uses computing resources to achieve its goals and to transform how it reaches these goals. The older and more established discipline IS has existed since the 1960s. Its focus from the beginning has been organizational computing in a business context, with a specific emphasis on how changes in business processes and information management transform the way business is conducted. IT emerged as an independent academic discipline during the last decade, primarily through its contribution to undergraduate education. IT also focuses on the organizational context, but it primarily addresses questions related to the technology infrastructure.

This handbook set has numerous elements that discuss the nature and identity of the IS and IT disciplines (such as the Preface to Volume I, and see Chapters 1 through 5 in this volume). We will not attempt to replicate that conversation here; it is, however, safe to say that neither discipline has even internally converged into a fully unified understanding of its own identity. Throughout its almost 50 year history, the IS discipline has continuously debated its identity (see Chapter 1 in this volume). The same process has now begun for IT. We hope that this volume will contribute to the disciplinary processes that seek for clarity regarding the identities of both IS and IT.

When referring to organizational units and capabilities, the terms "information systems" and "information technology" are, in practice, used interchangeably. Even the research literature is often incapable of separating them in a consistent way. We would have liked to follow a consistent approach where IT refers primarily to the technology infrastructure and IS to the application of the technology in an organizational context, but doing so would have imposed overly restrictive constraints, given the current practice in the field. Therefore, we ask for your patience particularly in the context of management of IS capabilities—the use of these terms is not always systematic between (or even within) the chapters. Sometimes, we resort to the IS/IT moniker when we want to specifically acknowledge a consistent practice of using both terms interchangeably.

This volume of the *Computing Handbook Set* has nine parts, which collectively demonstrate the richness and breadth of the IS and IT disciplines and their close linkages to the practice of using, managing, and developing IT-based solutions to advance the goals of their environments. As the entire handbook set, this volume is targeted to both academics and practitioners. On the one hand, the chapters provide academic readers with introductions to the current status and future directions of academic research in the topic areas of the chapters. On the other hand, the chapters give advanced practitioners in-depth perspectives on the contributions of academic research to the practice of IS and IT development, use,

and management. In this preface, we will first explain the background for the structure of the volume and then provide brief introductions to the core content of each of the parts of the volume. We conclude the preface by acknowledging and thanking the people who have been instrumental in making this effort possible.

Structure of the Volume

This volume includes nine parts: (I) Disciplinary Foundations and Global Impact; (II) Technical Foundations of Data and Database Management; (III) Data, Information, and Knowledge Management; (IV) Analysis, Design, and Development of Organizational Systems; (V) Human–Computer Interaction and User Experience; (VI) Using Information Systems and Technology to Support Individual and Group Tasks; (VII) Managing and Securing the IT Infrastructure and Systems; (VIII) Managing Organizational Information Systems and Technology Capabilities; and (IX) Information Systems and the Domain of Business Intertwined.

The selection of chapters and topic categories for this volume is based on an editorial decision process that integrates several perspectives. As with Volume I of this handbook set, this volume pays close attention to the undergraduate model curricula developed by ACM (in collaboration with AIS in the case of IS) for these disciplines. The latest IS model curriculum IS 2010 (Topi et al., 2010) identifies the following core topics: foundations of IS (Part I); data and information management (Parts II and III); enterprise architecture, IS project management, IT infrastructure (Part VII); systems analysis and design (Part IV); and IS strategy, management, and acquisition (Parts VIII and IX). Five of them (with slightly different titles) are directly implemented as parts of this volume, and the remaining two (enterprise architecture and IS project management) have their own chapters. The IT curriculum recommendation IT 2008 (Lunt et al., 2008) has a strong emphasis on human–computer interaction (HCI), information assurance and security, information management, system administration and management, and system integration and architecture. HCI has its own part in this volume (Part V), and data and information management two others (Parts II and III); the other core IT topics are covered in Part VII.

The curriculum recommendations were not, however, the only source of guidance for the structure of this volume. Several recent articles explore the identity of the IS discipline (e.g., Sidorova et al., 2008; Taylor et al., 2010); of these, particularly Sidorova et al. provides a useful high-level categorization that supports the structure that had emerged from the curriculum reports. The high-level categories in Sidorova et al. are IT and organizations (covered primarily in Part IX, but also in Part VIII), IS development (primarily Parts IV and V, but also Parts II and III), IT and individuals (Part VI), IT and markets (also Part IX), and IT and groups (included in Part VI). The final structure was formed iteratively throughout the development process. Our hope is that it serves as helpful conceptual framework for structuring the rich set of materials included in this handbook.

Introduction to the Parts of the Volume

A summary of the major contents of each of the nine parts of this volume is given next. Readers should feel free to engage these parts in any order they prefer.

Disciplinary Foundations and Global Impact

Part I, Disciplinary Foundations and Global Impact, explores the identity, characteristics, and boundaries of the IS and IT disciplines. In addition, it positions IS and IT in the societal context and discusses the opportunities IT offers as an enabler of global development and social transformation.

Chapter 1 discusses the core topics and development of the discipline of IS based on an analysis of most widely cited articles throughout the history of the discipline. Chapter 2 covers the history and development of the emerging IT discipline. Chapters 3 and 5 provide alternative perspectives on the

identity, nature, and core theories of the IS discipline: Chapter 3 emphasizes the importance of the IT artifact and the connection to practice of IS development and management, whereas Chapter 5 focuses on the connection between IS and the social context in which they are used by introducing sociotechnical approaches to IS. Chapter 4 is one of the earliest published integrated reviews of principles, methods, and theories for the discipline of IT. Chapters 6 and 7 both explore the broader societal impact of information and communication technologies in the global context: the former discusses the role these technologies have in the global development processes, whereas the latter specifically focuses on digital divide through a case example.

Data and Information Management

One of the key focus areas of both the IS and IT disciplines is data and information management, an area that computer science also considers its own. In designing the *Computing Handbook Set*, we decided to locate the Technical Foundations of Data and Database Management (Part II) in this volume to keep it together with the chapters on Data, Information, and Knowledge Management (Part III). Both parts focus on issues related to the acquisition, storage, and retrieval of data, information, and knowledge. The perspective of chapters in Part II emphasizes on database design and implementation while Part III covers topics related to modeling, analyzing, and managing information.

Part II starts with a discussion on foundational data models (relational, semantic, object-oriented, and object-relational) in Chapter 8. It continues with topics related to the tuning of various aspects of database design to achieve high performance (Chapter 9). Chapter 10 covers fundamental access methods (B-tree with variations and extensions, and hashing), spatial access methods (specifically, R-tree), and advanced access methods topics. Chapters 11 and 12 address two additional essential technical data management topics: query optimization and concurrency control and recovery, respectively. In Chapter 13, the focus moves to issues that are particularly important for distributed and parallel database systems. Chapter 14 reviews the core computing questions related to the modeling, search, and storage of multimedia (image, audio, and video) data.

In addition to the technical data management issues discussed earlier, the broader topic of organizational data, information, and knowledge management includes a rich variety of essential practical and theoretical questions, which are covered in Part III. The part starts with a review of conceptual modeling, particularly focusing on the approaches that are built on the philosophical field of ontology (Chapter 15). Chapter 16 explores issues that are instrumental in ensuring organizational data and information quality. The following two chapters provide two different perspectives on the utilization of both structured and unstructured data: Chapter 17 includes a comprehensive overview of the area of knowledge management, covering both theoretical and practical issues, whereas Chapter 18 focuses on the management of digital content in digital libraries. The discussion continues with issues related to the effective use of large amounts of organizational data, in Chapter 19 in the context of knowledge discovery and data mining and in Chapter 20 with an emphasis on unstructured, very large and highly dynamic data sets under the umbrella of Big Data. The part concludes with a managerial perspective introduced in Chapter 21 that covers the high-level governance of organizational data and information.

Analysis and Design of Organizational Systems

Analyzing the requirements for and designing organizational IS has been a core element of the IS discipline since its early days in the 1960s. Part IV—Analysis, Design, and Development of Organizational Systems—provides comprehensive coverage extending from the role of IT as an enabler of organizational change to methods and approaches of systems analysis and design, as well as through topics such as enterprise architecture, business process management and analysis, and the impact of culture on IS design and use.

One of the topics that has been vigorously debated within the academic IS community is the role and importance of design for the discipline. Building on earlier seminal works in IS literature (such as Hevner

et al., 2004), Chapter 22 makes a strong case advocating the importance of design and design science for the discipline, providing guidance for conducting this type of academic work, and linking it to practice. The next two chapters explore the role of enterprise systems and enterprise architecture as enablers of organizational transformation, separating the impact of large core systems from systems that improvise at the edges beyond the core. Chapter 23 has a more general focus on IT as an enabler of new opportunities, whereas Chapter 24 specifically presents a review of issues related to enterprise systems. Enterprise architecture has become an increasingly important topic within the IS field (as demonstrated by its inclusion in the undergraduate model curriculum in IS 2010), and, thus, it is natural for this volume to include a chapter on this topic (Chapter 25). The part continues with two chapters that explore the two key aspects of any systems specification effort: business process management and analysis (Chapter 26) and information requirements determination (Chapter 27). Chapter 28 provides an overview of the development of systems analysis and design approaches over the lifetime of the IS discipline, and Chapter 29 explores the systems development process with an emphasis on the individual developer's perspective. Chapter 30 is a high-level overview of the development and management of complex, large-scale information infrastructures. The part concludes with a review of a more specialized topic in Chapter 31, which studies the impact of culture on IS design, particularly in the context of e-business.

Human–Computer Interaction and User Experience

The shared interests of IS and IT are again in focus in Part V—Human–Computer Interaction and User Experience. The interaction between human users and IT systems is an area that IS, IT, and computer science (CS) all explore from their own perspectives that are connected but distinct. The chapters in this part represent mostly viewpoints that come from HCI and usability practice and from research communities connected to the disciplines of computer science, human factors, cognitive psychology, and industrial design.

Chapter 32 starts the part with a comprehensive overview of usability engineering, an important core area within HCI. The chapter provides a framework and offers process guidance for designing highly usable systems. Chapter 33 covers the role of detailed task analysis in the process of designing usable functionality. The following chapters focus on specific issues and contexts within the broad area of HCI: the design of multimedia applications (Chapter 34), the role of international usability standards in supporting the development of highly usable systems (Chapter 35), and the design of web applications (Chapter 36). The part ends with Chapter 37, which summarizes, analyzes, and supports the recent calls to transform the discipline so that its focus will be increasingly on a broader user experience (UX) concept with a full range of psychological, social, cultural, physiological, and emotional elements.

Using Information Systems and Technology to Support Individual and Group Tasks

Part VI—Using Information Systems and Technology to Support Individual and Group Tasks—also explores questions regarding the relationship between individual users (or groups of users) and IT solutions. This part represents perspectives and approaches most often associated with the IS discipline. Its chapters explore questions regarding the adoption and acceptance of technology by individuals, factors that influence the effectiveness of individuals' use of technology, and the development of individual users' computing capabilities. Another important broad topic area covered in this part is the use of IT to enable collaborative work through general communication capabilities and specifically designed task support.

Chapter 38 starts the part with a review and assessment of the research stream that is by far the most widely cited in IS (see Chapter 1): technology acceptance and adoption at the individual level. The chapter also articulates new opportunities for future research contributions in this area. The part continues with two chapters that consider the nature and development of individual capabilities in the use of IT. Chapter 39 explores the concept of computer self-efficacy (based on social cognitive theory), its impact on IT use and learning, and its continued importance even in the era of digital natives. Chapter 40 reviews

issues related to the development of individual computing capabilities and provides an integrative framework to support future research and practical applications in this area.

Chapter 41 analyzes the literature on trust, a concept that has strong impact on the acceptance and continued use of IT solutions. One of the task categories most commonly supported by IT is decision making, and Chapter 42 gives a general overview of cognitive aspects of decision making and a summary of IT-based decision aids that are used to support it. The remaining chapters in this part emphasize collaborative processes. Chapter 43 reviews literature on computer supported collaborative work, a field that explores how computing technologies influence human collaboration at various levels. Within that same context, two specific forms of joint action at the team level—problem solving and decision making—are the focus of Chapter 44, which also reviews an influential long-term stream of IS research on group support systems. The remaining two chapters in this part explore organizational adoption of IT-based communication technologies, such as e-mail, text messaging, instant messaging, blogging, wikis, and other social media. Chapter 45 provides a broad, comprehensive overview on communication and collaboration technology adoption, whereas Chapter 46 takes a more focused view on internal use of social media.

Managing and Securing the IT Infrastructure and Systems

Part VII—Managing and Securing the IT Infrastructure and Systems—brings us to another broad topic area in which the disciplines of IS, IT, and CS share interests. The chapters explore issues related to organizing and managing IT infrastructure solutions so that both individual and organizational users can expect to have reliable and secure computing capabilities at their disposal without interruptions. The perspectives of the chapter vary from highly detailed technical to broadly managerial, but all of them share the focus on system continuity, reliability, security, and privacy.

Chapter 47 explores the role of different types of virtualization as key underlying capabilities of contemporary IT architectures. Building on the same conceptual ideas but at a higher level of abstraction is Chapter 48 on cloud computing and its implications on IT infrastructure development and acquisition. Computing has become pervasive and highly mobile, and this has a strong impact on the management of IT and its impact on enterprise characteristics, as described and discussed in Chapter 49 on enterprise mobility. Because of the pervasiveness and continuous need to have IT solutions available, it has become increasingly important to provide these technical capabilities in a sustainable way, as argued in Chapter 50. Chapter 51 reviews the characteristics and capabilities of organizational IT that make it possible to ensure business continuity in a computing-dependent environment.

The second half of Part VII focuses on security, starting from an overview of the technical foundations of IS security (Chapter 52) and continuing with an analysis of special requirements for securing organizational database resources (Chapter 53) and a policy-level review of information security from the behavioral and managerial perspective (Chapter 54). Chapter 55 explores the interaction between user privacy and system security with a focus on understanding the factors that affect privacy in digital business. Part VII concludes with Chapter 56 on digital forensics, a cross-disciplinary area that studies the identification, extraction, and analysis of digital artifacts for investigative purposes.

Managing Organizational Information Systems and Technology Capabilities

The emphasis shifts from systems and technology to organizations and management in Part VIII—Managing Organizational Information Systems and Technology Capabilities. The chapters in this part are all related to the management, organization, acquisition, development, and evaluation of people and IT as resources that make it possible for organizations to achieve their goals. Many of the chapters explore the processes that bring people and technology together as effectively as possible to serve the goals that the organization is striving to attain.

Chapter 57 reviews the current state-of-the-art understanding of how the IT function should be organized and configured in the broader context of an organization. The chief information office's (CIO)

role as a bridge between the broader organizational context and the IT function is continuously evolving, and Chapter 58 makes the case for the contemporary CIO's role as a business integrator and innovator. Within the internal IT organization, various IT management frameworks (for IT governance, IT service management, information security management, and IT project management) have become increasingly important and widely used tools. Chapter 59 provides a broad review of these frameworks, with a particular focus on COBIT (governance), ITIL (service management), and ISO/IEC 27000 series (security management).

Chapter 60 builds on a long-term research stream on IT outsourcing and offshoring and presents an overview of scholarly work related to sourcing of IT services. IT project management has been identified as one of the most important capabilities for IS/IT professionals; Chapter 61 reviews core research and practice issues related to this topic area. The next two chapters are both related to human resource management in IS/IT: Chapter 62 focuses on development and retention of computing professionals in organizations, and Chapter 63 reviews what is known about the evaluation of the performance of IS/IT professionals. The part concludes with Chapter 64 on IS audit practices in the context of financial IS.

Information Systems and the Domain of Business Intertwined

This volume concludes with Part IX—Information Systems and the Domain of Business Intertwined—in which the chapters directly focus on the planning, use, organization, and selection of IS solutions in a way that optimally supports the organizational goals and leads to the discovery of new organizational opportunities. The chapters in this part are specifically focused on the application domain of business.

The part starts with Chapter 65 on strategic alignment, emphasizing a topic that IS executives have consistently found to be among the most important for them, that is, how to ensure that organizational IS and technology resources are fully aligned with the overall strategic goals of the organization. Chapter 66 explores IS strategizing and its development over the history of organizational use of IS, proposing a five-component framework for IS strategizing: IS strategy context, IS planning process, intended strategy, IS strategy impact, and emergent strategy. Chapter 67 reviews the literature on the relationship between IT and organizational characteristics, such as extent of centralization, size, and emergence of new organizational forms. It summarizes the research findings and suggests that there are practical implications to be considered in organizational IT planning and design.

Recent advances in computing and communication technologies have had a wide-ranging impact on a variety of organizational practices and capabilities. One of the areas affected strongly is innovation management. Chapter 68 demonstrates how open innovation processes enabled by IT-based infrastructure capabilities are becoming mainstream and radically change how organizations innovate. Chapter 69 explores another phenomenon that has been strongly affected by ubiquitous communication capabilities between organizations: interorganizational information systems (IOS). The chapter shows how IOS have transformed both industries and the way organizations conduct business, but it also identifies the areas where IOS implementations have been more rare and less successful.

The remaining three chapters of Part IX focus on organizational outcomes of IS. Chapter 70 builds directly on one of the most widely cited streams of IS research and presents a review of the current status of research on IS success. The chapter demonstrates that there are still significant opportunities for moving this rich research tradition forward and that both academics and practitioners can benefit from a deeper understanding of the definition of IS success and the factors affecting its achievement. Chapters 71 and 72 come from an important area within the IS discipline that uses the methods and conceptual models of economics to understand the economic impact of IT investments. Chapter 71 reviews and summarizes the literature on the business value of IS investments, pointing out the need to evaluate IS human resources and technology investments synergistically. Chapter 72 concludes the part and the book with a parallel but different view on the impact of IT on firm value, with a specific focus on the evolution of our collective understanding of this phenomenon, exploration of key paradox concepts (productivity and profitability), and an analysis of future directions.

Acknowledgments

This volume would not have been possible without the tireless and dedicated work of the authors. We feel fortunate and are very thankful for the willingness of both established leading experts and influential younger researchers to join this effort and contribute their expertise to the process. Many of the authors are recognized international leaders within their areas of study. Overall, the chapters incorporate and bring to the readers an unparalleled level of expertise and deep insights.

We would also like to thank the editorial staff at Taylor & Francis/CRC Press, particularly the persistent and gentle leadership of Randi Cohen, computer science acquisitions editor, whose role has extended beyond any reasonable call of duty. Bob Stern, as the original computer science editor who helped create this handbook in its original and second editions, also deserves recognition for his continued support over the years.

Heikki gratefully acknowledges the support of Bentley University—without his sabbatical, Heikki's work on this project would not have been possible. Most of Heikki's work took place while he was visiting at Aalto University School of Business in Helsinki, Finland; he thanks the Information Systems Science Group at Aalto for their collegiality and support. Overall, Heikki acknowledges the advice and help from a number of colleagues throughout the project. Most importantly, he extends his sincere thanks to his wife, Anne-Louise, and daughters, Leila and Saara, who patiently accepted and lovingly supported the long hours and periods of very intensive work that a project like this requires!

Allen acknowledges Bowdoin College for providing the time and support for him to develop the first, second, and third editions of this handbook set over the last 15 years. He also thanks the many colleagues who have contributed to this handbook and/or provided valuable advice on its organization and content throughout that period. Finally, he thanks his wife, Meg, and children, Jenny and Brian, for their constant love and support over a lifetime of teaching and learning.

We hope that this volume will be actively and frequently used both by academics who want to explore the current status and new opportunities within specific research areas and by advanced practitioners who want to understand how they can benefit from the latest thinking within the disciplines of information systems and information technology. We also warmly welcome your feedback.

Editors

Dr. Heikki Topi is professor of computer information systems at Bentley University in Waltham, Massachusetts. He earned his MSc in economics and business administration (management information systems) from Helsinki School of Economics in 1991 and his PhD in management information systems from Indiana University Graduate School of Business in 1995. Prior to his current role, he served at Bentley as associate dean of business for graduate and executive programs and as chair of the Department of Computer Information Systems. His other academic appointments include associate dean (MBA Program) at Helsinki School of Economics and Business Administration and visiting assistant professor at Indiana University. His teaching interests cover a range of topics, including advanced systems analysis and design, systems modeling, data management, and IT infrastructure. His research focuses on human factors and usability in the context of enterprise systems, information search and data management, and the effects of time availability on human–computer interaction.

Dr. Topi's research has been published in journals such as *European Journal of Information Systems*, *JASIST*, *Information Processing & Management*, *International Journal of Human–Computer Studies*, *Journal of Database Management*, *Small Group Research*, and others. He is the coauthor of a leading data management textbook, *Modern Database Management*, with Jeffrey A. Hoffer and V. Ramesh, and has served as the coeditor of Auerbach's *IS Management Handbook*, with Carol V. Brown. He has contributed to national computing curriculum development and evaluation efforts in leadership roles (including IS 2002, CC2005 Overview Report, and as a task force cochair of IS 2010, the latest IS curriculum revision) since the early 2000s. He has been a member of ACM's Education Board since spring 2006 and has represented first AIS and then ACM on CSAB's board since 2005.

Allen B. Tucker is the Anne T. and Robert M. Bass Professor Emeritus in the Department of Computer Science at Bowdoin College, Brunswick, Maine, where he served on the faculty from 1988 to 2008. Prior to that, he held similar positions at Colgate and Georgetown Universities. Overall, he served for 18 years as a department chair and two years as an associate dean of the faculty. While at Colgate, he held the John D. and Catherine T. MacArthur Chair in Computer Science.

Professor Tucker earned a BA in mathematics from Wesleyan University in 1963 and an MS and PhD in computer science from Northwestern University in 1970. He is the author or coauthor of several books and articles in the areas of programming languages, natural language processing, and software engineering. He has given many talks, panel discussions, and workshop presentations in these areas and has served as a reviewer for various journals, NSF programs, and curriculum projects. He has also served as a consultant to colleges, universities, and other institutions in the areas of computer science curriculum, software development, programming languages, and natural language processing applications. Since retiring from his full-time academic position, Professor Tucker continues to write, teach, and develop open source software for nonprofit organizations.

A fellow of the ACM, Professor Tucker coauthored the 1986 Liberal Arts Model Curriculum in Computer Science and cochaired the ACM/IEEE-CS Joint Curriculum Task Force that developed

Computing Curricula 1991. For these and related efforts, he received the ACM's 1991 Outstanding Contribution Award, shared the IEEE's 1991 Meritorious Service Award, and received the ACM SIGCSE's 2001 Award for Outstanding Contributions to Computer Science Education. In 2001, he was a Fulbright Lecturer at the Ternopil Academy of National Economy in Ukraine, and in 2005, he was an Erskine Lecturer at the University of Canterbury in New Zealand. Professor Tucker has been a member of the ACM, the NSF CISE Advisory Committee, the IEEE Computer Society, Computer Professionals for Social Responsibility, the Liberal Arts Computer Science (LACS) Consortium, and the Humanitarian Free and Open Source Software (HFOSS) Project.

Disciplinary Foundations and Global Impact

1

Evolving Discipline of Information Systems

Heikki Topi
Bentley University

1.1 Introduction

This chapter gives its readers an overview of the Information Systems (IS) discipline and discusses how the discipline has evolved during in its relatively brief history. To achieve this goal, it uses two approaches: first, an analysis of the most highly cited articles within the discipline and second, an introduction to broad, self-reflective scholarly conversations that have taken place within the discipline.

This chapter does not, however, intend to present a comprehensive history of the field. There are many reasons underlying this choice. One of the most important ones is the recent *Journal of Association for Information Systems* special issue on the history of the IS field published in 2012 (Hirschheim et al., 2012). Particularly an article by Hirschheim and Klein (2012) provides a very thorough and comprehensive historical analysis of the IS field. It would be difficult, if not impossible, to add anything substantive to its 50 pages written over a 12 year period (Hirschheim et al., 2012, p. iv) in a short book chapter. Despite its length and depth, the Hirschheim and Klein (2012) article is highly readable, and it is an excellent starting point for anybody who wants to understand where the IS field came from, where it currently is, and where its future could be. A more condensed version of this history is available in Section 1.2.2 of Hirschheim and Klein (2003).

The analytical approaches chosen for this chapter have two goals: First, the chapter wants to provide its readers with an overview of the topics that have been most influential in the course of the history of the IS field. Second, the chapter introduces a contextual structure that helps in positioning the chapters in this volume in the broader context of the field. Both the analysis of the highly cited articles and the review of the broad conversations provide insights regarding the topics that the field itself and those using its results have considered most important.

1.2 Analysis of Most Highly Cited Scholarly Work in Information Systems

The first approach to describing the discipline of IS is based on a comprehensive attempt to identify about 100 most highly cited articles published by IS scholars at any time during the field's history. These scholarly works are then used to discover the patterns they reveal about the core topics and areas of interest within the field. There is no straightforward way to identify the pool of all scholarly articles within the IS field, and thus, a number of mechanisms were used to add articles to this pool. The first was to approach the problem through highly cited scholars and assume that their most highly cited articles would be among the target group. Consequently, one of the starting points for forming the article pool was Hu and Chen's (2011, Table 1.1) list of 85 highly productive IS researchers with high H index values. The other approach to forming the pool was to identify key IS journals and choose the most highly cited articles for each of them. The journals included the premier journals chosen by the IS senior scholars (in alphabetical order: *European Journal of Information Systems*, *Information Systems Journal*, *Information Systems Research*, *Journal of AIS*, *Journal of Information Technology*, *Journal of MIS*, *Journal of Strategic Information Systems*, and *MIS Quarterly*). In addition to these eight, *Decision Sciences*, *Decision Support Systems*, and *Management Science* were covered. Moreover, the citations for key articles of well-known authors not included in the first group were also evaluated. It is possible that this approach left out published works that should have been included, but it is likely that these would not have had a material impact on the story that the data tell.

TABLE 1.1 Classification Categories

	Category	Sum of Citation Index Values	Total Number of Articles	Average Citation Index Value
1.	User acceptance and use of IT	15,918	23	692
2.	Impact of IT on organizations	4,107	11	373
3.	Methodology	3,407	8	426
4.	Media and organizational communication	3,292	6	549
5.	Knowledge management	3,265	7	466
6.	IS success	2,628	4	657
7.	IT and business performance	2,619	7	374
8.	Trust	2,552	7	365
9.	Electronic marketplaces	1,962	4	491
10.	Adoption	1,881	3	627
11	Group support systems	1,843	4	461
12.	User satisfaction	1,375	3	458
13.	Design science	1,027	2	514
14.	IT implementation	1,019	3	340
15.	Self-efficacy	946	2	473
16.	Managerial IT use	761	2	381
17.	Artificial intelligence	701	1	701
18.	Coordination	647	1	647
19.	Enterprise systems	595	1	595
20.	IS continuance	365	1	365
21.	Discipline identity	356	1	356
22.	Data quality	316	1	316
23.	IS effectiveness	256	1	256
24.	Outsourcing	224	1	224
25.	Electronic commerce	173	1	173

The citation counts were retrieved from two sources: Google Scholar (using Publish or Perish; see Harzing, 2007) and Social Science Citation Index (SSCI). The citation counts were retrieved during a single day in June 2012. The value used in this analysis for ranking purposes was based on the formula (Google Scholar count/4 + SSCI count)/2. Obviously, this is not an attempt to determine a real citation count; instead, it provides a citation index that gives more weight to the SSCI count but still takes into account the significantly higher nominal values of Google Scholar (see Meho and Yang, 2007 for a justification to use both Google Scholar and SSCI). The citation counts have not been adjusted based on the publication year; this analysis will naturally leave out the most recent influential articles. This is not a problem, given the purpose of this chapter, which intends to identify the themes and topics that the field of IS has focused on and contributed to over its history.

Using an arbitrary cutoff point of 1000 Google Scholar citations, the analysis identified a list of the 105 articles, which is in Appendix 1.A. In addition to the year, author, and journal information, the table also presents a categorization for each of the papers. The categories used in this analysis are at a lower level of abstraction than, for example, those derived in Sidorova et al. (2008), because the purpose of the analysis was to illustrate the scholarship topics that the most highly cited IS articles during the past 30 years represent. The author of this chapter categorized the articles based on their title and abstract; if necessary, the full article was used to determine the proper category. The categorization and category development process was iterative: during the first round, each article was assigned to an initial category, which was potentially modified for clarity and consistency during subsequent rounds.

In this chapter, the focus is on the content of the most highly cited articles (instead of, for example, the authors or the institutions). Again, the purpose is to demonstrate through the most actively used scholarly contributions what topics the IS field, those external fields benefiting from it, and the practitioner community value most highly based on the use of the scholarship. Next, the key categories discovered in the analysis will be described.

1.2.1 Description of Identified Categories

Table 1.1 includes a list of the categories that emerged from the classification process; in addition to the category name, the table includes the sum of citation index values for the articles in the category, the number of articles in each category, and the average of citation index values in each category. The categories are sorted by the sum of the citation index values.

The rest of the section will discuss the key characteristics and the most important research themes featured in each of the categories.

1.2.1.1 User Acceptance and Use of IT

By far, the most actively cited category is *user acceptance and use of information technology (IT)*. The seminal works in this category are Davis (1985, 1989) and Davis et al. (1989), which introduced the Technology Acceptance Model (TAM). These articles were then followed up by a number of influential efforts to evaluate and extend TAM, such as Taylor and Todd (1995b), Gefen and Straub (1997), Venkatesh and Davis (2000), and Venkatesh et al. (2003). Applications of TAM to various contexts have also had a strong impact and been cited widely (e.g., Koufaris, 2002; Gefen et al., 2003; Pavlou, 2003). The field as a whole has spent a significant amount of time and effort discussing the contributions and the future of TAM (including a special issue in the *Journal of AIS*; Hirschheim, 2007). The core premise of TAM is simple: it posits that the probability of a user's behavioral intention to use a specific IT is based on two primary factors: perceived usefulness and perceived ease of use, the former directly and the latter both directly and mediated by perceived usefulness. The research building on the seminal articles over a period of 25 years has expanded the scope significantly and made the theory much more complex. TAM and related research specifically focus on individual users.

TAM has been so dominant that it has become the default conceptual model for any research on antecedents of IT adoption and use. For example, when Agarwal and Karahanna (2000) introduced

an instrument for measuring the level of user's cognitive absorption with software (in their case, a web browser) and studied its impact on use, it appears that the choice to use TAM constructs to model the mediating variables between cognitive absorption and intention to use was, in practice, automatic. Thompson et al. (1991) proposed an alternative model for understanding use based on Triandis (1980). Even at that time, just a couple of years after the seminal TAM papers were published, the authors already positioned the reporting of their results as a comparison with TAM.

In addition to technology acceptance research discussed earlier that has focused on the antecedents of intention to use, IS researchers have also studied individual use of IT and its antecedents and consequences from other perspectives (often directly linked to TAM). Goodhue and Thompson (1995) introduced a model entitled "Technology-to-Performance Chain" and as part of it the task-technology fit model. Their article integrates two insights into one model: first, to have an impact on individual performance, a specific technology artifact must be used, and second, it has to have a good fit with the task in the context of which it is used. The study found strong empirical evidence to support these propositions that formed an important foundation for the stream of research that was based on it.

The dominance of TAM and the broader acceptance and use of IT category in IS research are also demonstrated by the citation metrics—articles related to user acceptance and use have a higher total citation index value than the following four categories together. These articles count for about 30% of the total of the citation index values in the top 105 articles. Some researchers (such as Benbasat and Barki, 2007) have questioned whether or not the strong focus on TAM has led to nonoptimal resource allocation patterns for the discipline.

This volume includes a comprehensive analysis of the current status and future opportunities of the individual technology acceptance research by Venkatesh et al. (Chapter 38). This chapter and the JAIS 2007 special issue (Hirschheim, 2007) are excellent starting points for a reader who wants to build a strong foundation for understanding this essential stream of research.

1.2.1.2 Impact of IT on Organizations

The second most widely cited category is labeled *Impact of IT on organizations,* and it is dominated by Wanda Orlikowski's work. Most of the articles in this category provide perspectives on and guidance for studying, understanding, and making sense of the role of IT in organizations (e.g., Orlikowski and Baroudi, 1991; Orlikowski and Gash, 1994). Many of them follow a structurational perspective, which, based on the structuration theory by Giddens, explores how structures emerge from the interactions between the users and the technology (Orlikowski and Robey, 1991; Orlikowski, 2000). For this perspective, it is particularly important to understand how the use of technology contributes to and is associated with innovation, learning, improvisation, and emergent practices in organizations. One of the key insights revealed through this stream of research is the essential role of unintended and unplanned uses of technology and the strong impact these uses have on organizations. Technology and its users interact within organizations in a myriad of highly complex ways, and the users' reactions to technology and technology-based solutions are typically impossible to fully anticipate. In this volume, Sawyer and Jarrahi (Chapter 5) discuss structuration at a more detailed level.

The articles that focus specifically on IT and organizational change form an important subcategory. Some of them explore the theories of and methods for analyzing and understanding the relationship between technology and organizational change. For example, Markus and Robey (1988) review the theories about the impact of technology on organizations with an explicit intent of improving the qualities of these theories. Orlikowski and Robey (1991), in turn, suggest a theoretical framework (based on Giddens' structuration theory) for guiding studies on two areas that are closely linked to IT-enabled and induced organizational change: systems development and the effects of IT use on organizations. Orlikowski (1993b) takes a closer look at the role of specific systems development tools (CASE tools) in organizational change processes. In another widely cited paper, she (Orlikowski, 1996) provides a detailed look at how small, frequently repeated actions by organizational actors while making sense of a new IT and applying it to their everyday work lead to organizational change.

In this volume, Markus discusses the complex relationship between IT and organizational structure (Chapter 67). Jarvenpaa's chapter on open innovation management illustrates the very significant impact IT has had on the development of innovation management, an essential organizational capability (Chapter 68).

Returning back to the highly cited articles, two papers in the IT and organizational change subcategory take quite a different approach from the ones discussed earlier. Both Henderson and Venkatraman (1993) and Venkatraman (1994) are more prescriptive in their approach, explicitly providing guidance regarding the ways IT can be used to enable certain types of organizational transformation processes. Henderson and Venkatraman (1993) also suggest an important mechanism for understanding and guiding the alignment between IT and business strategies (strategic integration) and the fit between business and IT infrastructures (functional or operational integration). Venkatraman (1994) presents a five-level model to describe different types of IT-enabled business transformation, starting from localized exploitation and moving through internal integration, business process redesign, and business network redesign to business scope redefinition.

In this volume, several chapters discuss related issues, including Luftman on alignment (Chapter 65), and both Rossi & Lindman and Devadoss the relationship between organizational transformation processes and the design, implementation, and use of large-scale enterprise systems (Chapters 23 and 24, respectively).

1.2.1.3 Methodology

The next most widely cited main category of IS research articles consists of those providing guidance on *methodology* to the community. The most influential articles have covered case research (Benbasat et al., 1987; Walsham, 1995), interpretive field studies (Myers, 1997; Klein and Myers, 1999), structural equation modeling (Chin, 1998; Gefen et al., 2000; Chin et al., 2003), and instrument validation (Straub, 1989).

1.2.1.4 Media and Organizational Communication

The list of frequently cited article categories continues with *media and organizational communication*. In this category, by far the most influential paper is Daft and Lengel's (1986) study on the reasons why organizations process information and the relationship between structure, media characteristics (specifically, media richness), and organizational information processing. A common general theme within this category is the impact of communication media on organizational communication effectiveness. The emergence of e-mail and its impact on managerial communication has been of particular interest (Sproull and Kiesler, 1986), together with media selection (Daft et al., 1987). Markus (1987) and Yates and Orlikowski (1992) have produced widely used general analyses of interactive media and genres of organizational communication, respectively.

1.2.1.5 Knowledge Management

Knowledge management is the next highly influential category. In this area, a review article by Alavi and Leidner (2001) is clearly the most widely cited contribution to the literature, demonstrating the usefulness of high-quality integrative summaries (see also Alavi and Leidner, 1999). Alavi and Leidner also articulate the key positions of the longstanding debate regarding the relationship between data, information, and knowledge, an essential question when the focus is on understanding how knowledge management differs from and depends on information and data management. Davenport et al. (1998) have contributed another broadly used (although significantly more practically focused) review article, which emphasizes the importance of knowledge management projects and explores their success factors. The factors that motivate individuals within an organization to share their knowledge and contribute it to the relevant organizational knowledge management systems have been a specific question of interest, explored by Wasko and Faraj (2005) and Bock et al. (2005).

In this volume, Newell and Marabelli (Chapter 17) provide a comprehensive overview of the current status of knowledge management research and practice.

1.2.1.6 IS Success

The meaning, role, and importance of *IS success* is the focus of four highly influential articles that have explored the question of what it means to achieve success with IS. The seminal article in this area is DeLone and McLean (1992), which was later updated by the same authors 10 years later (DeLone and McLean, 2003). Seddon's respecification and extension of the original model (Seddon, 1997) has also reached a strong position as a widely cited article. The original DeLone and McLean paper identified six interdependent IS success constructs: system quality, information quality, use, user satisfaction, individual impact, and organizational impact. These constructs are organized into a process model with organizational impact as the ultimate IS success construct affected either directly or indirectly by the others. The updated 2003 model added a third quality dimension, service quality, recognized the connection between intention to use and use, and replaced all impact measures with a single net benefit construct.

DeLone, McLean, and Sedera continue to build on their earlier work, evaluate its impact, and propose new directions for future work in Chapter 70 of this volume.

1.2.1.7 IT and Business Performance

Another significant area of interest in IS research is the relationship between *IT and business performance*, often explored using the methods and approaches of economics. Two highly influential papers in this category (Mata et al., 1995; Bharadwaj, 2000) have adopted the resource-based view of the firm as the underlying perspective for exploring the role of IT as a source of competitive advantage. Mata and colleagues concluded that of the five factors that they analyzed conceptually, only one (managerial IT skills) is likely to be a source of competitive advantage; the others (access to capital, proprietary technology, technical IT skills, and customer switching costs) do not satisfy the criteria that would grant them this role. Bharadwaj (2000) categorizes IT resources into three groups: IT infrastructure, human IT skills (managerial and technical), and IT-enabled intangibles (such as customer orientation, knowledge assets, and synergy). Based on an empirical analysis, she comes to a different conclusion compared to Mata et al., stating that "IT capability is rent generating resource that is not easily imitated or substituted" (p. 186), attributing the ability to sustain superior performance to time compression diseconomies, resource connectedness, and social complexity.

Two authors who have contributed very significantly to the discussion regarding the relationship between IT and business performance are Brynjolfsson and Hitt. In this analysis, four of their articles were included among the most highly cited ones: Brynjolfsson and Hitt (1996, 2000), Hitt and Brynjolfsson (1996), and Brynjolfsson (1993). Two of them (Brynjolfsson, 1993; Brynjolfsson and Hitt, 1996) analyzed the widely cited productivity paradox of computing (which refers to the invisibility of the effects of IT in aggregate output statistics). By analyzing firm-level data, the authors discovered that IT spending (both capital and labor) had a significant impact on firm output and concluded that at least in their sample the paradox had disappeared. Brynjolfsson and Hitt (2000, p. 45) emphasized the role of IT as a "general purpose technology" that enables complementary innovations, such as new business processes and new organizational and industry structures. The authors further emphasized the importance of performing the analysis at the firm level instead of evaluating only economies or industries at the aggregate level.

In this volume, Chapter 71 by Hoadley and Kohli and Chapter 72 by Mithas and Lucas explore the questions related to the business value of IS/IT investments, each with their own distinctive perspective.

1.2.1.8 Trust

IS research on *trust* has achieved a highly visible status, gaining it the eighth place in this analysis. This category has two clearly different elements: trust within virtual teams (Jarvenpaa and Leidner, 1998; Jarvenpaa et al., 1998) and trust in the context of consumer electronic commerce or electronic markets (Jarvenpaa et al., 1999; Gefen, 2000; McKnight et al., 2002; Jøsang et al., 2007). These two streams are

connected through the trust construct itself, but the contexts and core issues are quite different. In the former, the key questions are related to the role of trust (or the lack thereof) in the context of globally distributed teams that are conducting work without the benefit of establishing personal relationships in a face-to-face environment. In the latter case, the focus is on the mechanisms through which virtual marketplaces and the organizations maintaining them can create trust that has the potential to alleviate the users' concerns regarding the risks associated with the marketplaces. In both cases, the scholarly work has improved our understanding of how trust is formed and maintained in environments where physical presence is missing.

This volume recognizes the importance of trust in the design and use of IS by including a dedicated chapter related to this topic area (Chapter 41 by Li).

1.2.1.9 Electronic Marketplaces

Moving forward in the list of categories of influential, highly cited articles, the next one focuses on *electronic marketplaces*. Malone et al. (1987) wrote a pre-electronic business (as we know it now) analysis of electronic markets and hierarchies, stating insightfully "We should not expect electronically interconnected world of tomorrow to be simply a faster and more efficient version of the world we know today. Instead, we should expect fundamental changes in how firms and markets organize the flow of goods and services in our economy" (p. 497). This has definitely been the case, and the transformation process is not over yet. A few years after Malone et al. (1987) and Bakos (1991) analyzed the potential strategic impact of electronic marketplaces, focusing on key dimensions of the impact of the digitalization of business: reduction of search costs, network externalities, technological uncertainty, switching costs, and economies of scale and scope (p. 308). Bakos (1997) takes a closer look at the reduction of buyer search costs and their impact on electronic marketplaces. Brynjolfsson and Smith (2000) compare conventional and Internet retailers to each other, with a specific focus on the impact on Internet retailing on pricing.

1.2.1.10 Adoption and Diffusion of IT Innovations

Adoption and diffusion of IT innovations has been an influential area of research, exemplified in our group of highly cited articles by Cooper and Zmud (1990), Moore and Benbasat (1991), and Karahanna et al. (1999). Cooper and Zmud studied the adoption (allocation of resources to acquire the innovation) and infusion (achieving high levels of effectiveness with the innovation) of an organizational innovation (material requirements planning systems, precursors of current ERPs), finding significant differences in factors that affect adoption compared to those affecting infusion. Moore and Benbasat focused on individual adoption of an IT, developing an instrument for measuring perceptions that might have an impact on the adoption process. Moore and Benbasat's work was strongly based on Rogers's theory of innovation diffusion (Rogers, 2003) and the five attributes of innovations identified by Rogers (relative advantage, compatibility, complexity, observability, and trialability). Both the instrument introduced in this article and the development process have been widely used. One of the adopters of the instrument was Karahanna et al. (1999), who examined at the individual-level pre-adoption and post-adoption beliefs and attitudes, demonstrating the fundamental importance of perceptions regarding usefulness and enhancing one's image post-adoption.

In the context of this volume, issues of technology adoption are most visible in Chapter 38 on individual-level technology adoption research by Venkatesh et al. and in Chapter 45 in which Grudin explores factors affecting the adoption of new communication and collaboration technologies in organizations. These chapters do not, however, incorporate the innovation diffusion perspective.

1.2.1.11 Group Support Systems

The next topic was prominently featured in the IS literature in late 1980s and early 1990s: *group (decision) support systems (GSS) and other collaborative systems*. The most highly cited paper in this category, DeSanctis and Poole (1994), could also have been categorized based on the way it introduces the adaptive structuration theory as an approach to study the role of technology in the context of organizational change. The empirical

context for the paper is, however, GSS (or GDSS, as the authors call it). The article presents seven propositions of the adaptive structuration theory and explores the applicability of the theory to the study of GSS use in a small group context. The key issue it highlights (in addition to the theoretical contribution) is that the introduction of the same technology may lead to widely different organizational outcomes and that the effectiveness of technology use is dependent on how it is appropriated at a specific organizational context. An earlier article by DeSanctis (DeSanctis and Gallupe, 1987) presents a framework for the study of GSS, demonstrating the importance of group size, the proximity of the group members, and the nature of the task as important contingency variables.

DeSanctis represents a GSS research tradition that emerged from the University of Minnesota; another very significant center for this research was the University of Arizona, where the work by Nunamaker and his research team led to a long stream of research contributions and software products in this area. The most highly cited of these articles is Nunamaker et al. (1991), which presents a summary of research conducted at the Arizona research program on electronic meeting systems (EMS). In addition to the framework for the study of these systems, the article gives a good overview of the Arizona approach that combines the design and implementation of technology artifacts with research on them both in the laboratory and in the field.

The current state of GSS research and the broader area of research on enhancing team-level problem solving and decision making is reviewed by de Vreede et al. in Chapter 44 of this volume. In addition, Poltrock provides a comprehensive overview of a closely related area, computer-supported cooperative work, in Chapter 43.

1.2.1.12 User Satisfaction

Before the emergence of the TAM research and focus on perceptions of perceived ease of use and usefulness, several papers were published on *user satisfaction*. Bailey and Pearson (1983) described the process of developing an instrument for measuring "computer user satisfaction." Despite the name, the construct itself has little to do with computers per se. Instead, the instrument appears to capture at a very broad level users' satisfaction with the services that the IT (EDP) department provides (the instrument includes questions related to, among others, top management involvement, charge-back method for payment for services, and relationship with the EDP staff with 36 other categories). This is understandable given the time when these data were collected (around the time when first PCs were introduced).

Ives et al. (1983) fine-tuned the Bailey and Pearson instrument and developed a short form of it. The scope of the issues that the two instruments measure is equally broad; interestingly, the authors suggest that the instrument can be used to "evaluate an IS or general systems development effort in an organization." Doll and Torkzadeh (1988) reported on the development of a different type of a satisfaction instrument, which was intended to focus on the users' satisfaction with the outcomes and ease of use of a specific application (instead of, say, the general satisfaction with the IS department). The resulting instrument was designed to capture data on five factors: content, accuracy, format, ease of use, and timeliness. Even though the seeds of the ideas underlying TAM are clearly included in this article, it is interesting to note that the work was parallel with that of Davis (whose dissertation was published in 1985).

1.2.1.13 Design Science

There are only two articles in the following category, *design science*, but particularly the more highly cited of them, Hevner et al. (2004), has already had a very impressive impact on research within the field despite its recent publication date. The popularity and influence of this article can be at least partially explained by its focus on an issue that is fundamental from the perspective of the identity of the IS field. It gave revived legitimacy for the design science paradigm in IS research at a time when many thought that only the behavioral research paradigm would survive. Hevner et al. built on earlier work, such as Nunamaker et al. (1990) and March and Smith (1995), the latter of which is the other highly cited article

in this category). Hevner et al. (2004) articulate a conceptual framework that positions IS research in the context of both the environment within which the accumulated body of knowledge is applied and the knowledge base that the research develops. They also specify a set of prescriptive guidelines for conducting design research.

Hevner provides an in-depth introduction to design science research and discusses its achievements and future in Chapter 22 of this volume.

1.2.1.14 IT Implementation

The final category with more than two articles is labeled *IT implementation*. The three articles in this category, Markus (1983), Kwon and Zmud (1987), and Orlikowski (1993b), all explore questions related to IS implementation from a broad perspective that acknowledges the richness and complexity of the factors which affect the successfulness of IT implementation in organizations. In one of the early classics of the IS literature, Markus (1983) compares three theories (people-determined, system-determined, and the political variant of interaction theory) regarding the causes of resistance against the implementation of a new IS and finds support only for the political variant of interaction theory. Kwon and Zmud (1987) present a stage model for IT implementation activities, and Orlikowski (1993) develops a theoretical framework that helps us understand a variety of "organizational issues" in the context of the adoption and use of CASE tools. The key lesson from all of these is that technical issues are seldom (if ever) the sole reason for difficulties or failures of IS implementation processes.

1.2.1.15 Other Categories

The remaining 11 categories of widely cited articles each have only one or two articles (in most cases one) and have a citation index value less than 1000. To keep the length of the material reasonable, these categories will not be discussed at a more detailed level.

1.2.2 Mapping of Categories of Interest to Prior Models

This section will briefly analyze the relationship between the categories identified in this chapter and discussed earlier (1–14) and those specified in two recent citation analysis–based articles that evaluate the status and development of the field of IS: Sidorova et al. (2008) and Taylor et al. (2010). Using different approaches, these articles provide a useful and interesting analysis of the identity of the field based on an analysis of published literature. Both analyses track the change of the field over time, demonstrating how the key areas of interest have changed.

As Table 1.2 shows, the mapping between Sidorova et al. (2008) and the categories identified in Section 1.2.1 is straightforward, particularly after two of our categories (*IS Success* and *Adoption and Diffusion of IT Innovations*) were divided into two new ones based on the level of analysis (individual vs. organizational). The most significant insight from this analysis is the dearth of articles on IS development among the most highly cited IS studies—the only category that fits at least partially with IS development is design science (in which both articles advocate for more research on design science and provide guidelines for it, instead of presenting empirical evidence). Based on our analysis, most highly cited articles in the field of IS do not cover topics that are related to analysis, design, or coding of system solutions. Overall, IT and organizations and IT and individuals dominate; IT and markets and IT and groups have two and one subcategories associated with them, respectively.

Mapping to Taylor et al. (2010) was significantly more difficult than completing the same process in the context of Sidorova et al. (2008), at least partially because of the broad and somewhat amorphous boundaries of Taylor's IS Thematic Miscellany and Qualitative Methods Thematic Miscellany categories. The results of the matching process are included in Table 1.3. Not surprisingly, IS Thematic Miscellany covers the largest number of subcategories, while the rest are distributed equally over the other categories.

TABLE 1.2 Mapping of Categories Identified in Our Citation Analysis with Sidorova et al. (2008)

Sidorova et al. (2008)	Current Chapter
IT and markets	• IT and business performance
	• Electronic marketplaces
IT and organizations	• Impact of IT on organizations
	• Knowledge management
	• IT implementation
	• IS success—Organizational
	• Adoption and diffusion of IT innovations—Organizational
IT and groups	• Group support systems
IT and individuals	• User acceptance and use of IT
	• User satisfaction
	• IS success—Individual
	• Adoption and diffusion of IT innovations—Individual
IS development	• Design science
[Across or outside Sidorova categories]	• Methodology
	• Trust
	• Media and organizational communication

TABLE 1.3 Mapping of Current Chapter Categorization with Taylor et al. (2010)

Taylor et al. (2010)	Current Chapter
Inter-business systems	• Electronic marketplaces
IS strategy	• IS success
	• IT and business performance
IS thematic miscellany	• IT implementation
	• Design science
	• User acceptance and use of IT
	• User satisfaction
	• Adoption and diffusion of IT innovations
Qualitative methods thematic miscellany	• Impact of IT on organizations
Group work and decision support	• Group support systems
	• Knowledge management
[Across Taylor categories]	• Methodology
	• Trust

1.2.3 Shift of Focus on Research Categories over Time

One interesting question worth exploring is the shifts in the topics on which the field has produced highly cited articles. Table 1.4 shows for each of the 5 year periods starting from 1980 and ending in 2009, eight (or fewer, if there total number of categories represented was smaller than eight) most highly cited categories and the total number of articles and the sum of the citation metric counts from that time period.

There are a few categories that have stayed highly influential throughout the timeframe that is being evaluated. The consistency with which *User acceptance and use of IT* has maintained its top position is remarkable: it held the top or the second position throughout the 1985–2004 time period, dropping to the second place only once. *Impact of IT on organizations* was also included in the top eight categories for each of the time periods in 1985–2004, but with much modest rankings (except 1990–1994 when it held the top position). Another topic area with a consistent high-visibility presence throughout the observation period is *IS success*, although its positions at the top have been more periodic, punctuated

TABLE 1.4 Shifts in Research Categories over Time

Time Period	Most Significant Categories during the Time Period	Total of Citation Index Values	Total Number of Articles
1980–1984	User satisfaction IT implementation IS success	3,548	4
1985–1989	User acceptance and use of IT Media Methodology Markets GSS User satisfaction Impact of IT on organizations IT implementation	23,735	17
1990–1994	Impact of IT on organizations User acceptance and use of IT Adoption GSS IS success Coordination IT and business performance Media	21,607	24
1995–1999	User acceptance and use of IT Methodology Trust Self-efficacy IT and business performance Knowledge management Impact of IT on organizations Enterprise systems	23,518	30
2000–2004	User acceptance and use of IT Knowledge management IT and business performance Trust Methodology Design science IS success Impact of IT on organizations	27,089	26
2005–2009	Artificial intelligence Knowledge management Trust	3,451	4

by highly influential articles in 1980–1984, 1990–1994, and 2000–2004. There has also been a consistent stream of influential articles on various aspects of *Methodology*.

Other categories have gained a high-impact status later and then maintained it. *IT and business performance* emerged in 1990–1994 and has stayed as a top category ever since. Both *Knowledge management* and *Trust* have stayed as highly influential areas of research since they entered the top topic rankings in 1995–2009.

Research on *User satisfaction* and *IT implementation* peaked in 1980s. *Media and organizational communication* and *Group support systems* were in the center of the discipline between 1985 and 1995;

research in these areas has not regained the same type of prominence later, although it will be interesting to see what impact a recent article by Dennis et al. (2008) will have, given that it builds heavily on the earlier media research tradition. In addition, several topics earned a visible position once based on one or two highly influential articles. These include *Electronic marketplaces* in 1985–1989 (Malone et al., 1987), *Adoption* in 1990–1994 (Cooper and Zmud, 1990; Moore and Benbasat, 1991), *Coordination* in 1990–1994 (Malone and Crowston, 1994), *Self-efficacy* in 1995–1999 (Compeau and Higgins, 1995; Compeau et al., 1999), *Design science* in 2000–2004 (Hevner et al., 2004), and *Artificial intelligence* in 2005–2009 (Adomavicius and Tuzhilin, 2005). These are obviously all important research areas, but still much less consistently prominent than those that have maintained top positions throughout the time period.

1.2.4 Summary

The analysis of the most highly cited articles in the field of IS demonstrates unequivocally the dominance of the research on *User acceptance and use of IT*. About 30% of the total citation index values to these top articles referred to this category, within which research based on the TAM and its derivatives (such as Unified Theory of Acceptance and Use of Technology or UTAUT; Venkatesh et al., 2003) dominates. As Venkatesh et al. describe both in this volume (Chapter 38) and in Venkatesh et al. (2007), TAM has been replicated in a variety of contexts to show its generalizability, its predictive validity has been demonstrated through a number of studies, it has been shown to perform better than competing models, and it has been expanded to study the antecedents of its key constructs. Despite (or maybe because of) the dominant position of TAM, the question about its value and future is controversial in the field of IS, as demonstrated, for example, by the *Journal of Association of Information Systems* special issue in 2007 entitled "Quo Vadis TAM—Issues and Reflections on Technology Acceptance Research" (Hirschheim, 2007).

While technology acceptance research focuses on individuals and their decisions regarding technology, the second highly influential research category, *The Impact of IT on Organizations*, specifically emphasizes issues at the organizational level. In this research, the key questions are related to the impact of IT on how organizations can and do change in the context of technology introductions and interventions. Particularly interesting are the unintended consequences that emerge when users find ways to appropriate the technology in ways that aligns with their goals, sometimes in a way that is very different from the designer's or management's intent.

Overall, the analysis in this chapter illustrates both the broad diversity of the research in the field and the dominance of some of the approaches. These results suggest the IS discipline strives to understand questions as diverse as the following (and naturally many more):

- Why do users choose to accept some technologies readily and others not at all?
- What are the mechanisms through which IT affects organizations and can be used to transform them?
- How do people make decisions regarding communication options using computer-based technologies?
- What structures, incentives, and technologies should organizations have in place to ensure success in knowledge management?
- How do we define and measure the success of IS in organizations?
- Do IT-based solutions really have a measurable impact on business performance?
- What impact do various technologies have on the formation and maintenance of trust in virtual environments?
- What are the special characteristics of electronic marketplaces and how do they operate?
- What are the factors that determine whether or not an individual or an organization adopts an IT solution and how an IT innovation spreads among individuals and organizations?

It is interesting to note that our analysis of the most influential papers in IS research included very few that are related to areas that many faculty members in the field consider to be its core and that form the key elements of the IS curriculum recommendations (see, e.g., Topi et al., 2010): data, database, and information management; systems analysis and design (the analysis, design, and implementation of systems that utilize computing technology); or IT infrastructure (design and implementation of computing artifact that provide either processing or communication capabilities).

1.3 Key Conversations within the Field

During its history, the IS discipline has engaged in a number of highly intensive conversations reflecting on its own identity and position in academia in which many of the leading authors of the field have participated. All these discussions consist of a number of connected journal articles and/or book chapters. There is no formal way of identifying these conversations in an exhaustive way and thus, while this chapter covers a few well-known representative examples of these dialogues, it makes no claims regarding completeness. The purpose is to use this as another mechanism to illustrate topics that have had in a central role within the IS community.

1.3.1 Rigor and Relevance

One of the most persistent topics discussed by the IS community is the question about the relevance of IS research and the relationship between relevance and scientific rigor. This conversation has been ongoing throughout the history of the field, punctuated by a number of highly intensive periods. One such period was the publication of a number of Issues and Opinions articles on this topic in the March 1999 issue of *MIS Quarterly*. Benbasat and Zmud (1999) made, without hesitation, a claim that most IS research "lacks relevance to practice," identified this as a significant weakness of the field, and suggested approaches for changing the situation. In an interesting response to Benbasat and Zmud (1999), Davenport and Markus (1999) agree that the problem exists but they believe that an even more profound change to the field is needed—instead of moving further in our desire to emulate other management disciplines, IS should use medicine and law as our role models. In another response, Lyytinen (1999) calls for large and heterogeneous research teams that are able to attack large-scale problems from multiple perspectives. He also suggests that this debate looks quite different depending on the geographic context (e.g., the United States vs. Europe).

The next major event in this ongoing discussion was a large number of opinion pieces published in CAIS in 2001 as a "special volume on relevance," following a particularly vigorous discussion on IS world (an electronic distribution list for the IS community). Given that the total number of articles in this particular conversation episode is close to 30, it is not possible to address all the issues covered at a detailed level or give justice to individual contributions. In his introduction to the special volume, Gray (2001) summarizes the outcomes of the conversation by identifying as common themes that IS research should be relevant and that practitioners do not read academic literature. The authors do, however, provide a wide variety of explanations regarding why this might be the case and what the field should do about the situation.

Over the past several years, this topic has been frequently discussed in articles published in top IS journals. For example, Rosemann and Vessey (2008) lamented the lack of progress in achieving a higher level of relevance despite the active conversations and provided specific guidance regarding the ways in which the IS community could improve the relevance of its research. They suggest a multilevel approach, which would address the problem at the institutional, project governance, and research process levels. They advocate for the use of the "applicability check" method as an integral part of the research process as a way to ensure that a research project achieves its relevance objectives. In another *MIS Quarterly* article, Klein and Rowe (2008) proposed modifications to the doctoral programs that would make them more attractive to professionally qualified students and potentially help them publish in forms and

outlets that are interesting to practitioners. Also in *MISQ*, Gill and Bhattacherjee (2009) found that the ability of the IS discipline to inform its constituents has declined, not improved, despite the high level of attention given to the question. They present five very specific proposals regarding actions the field should take in order to improve its relevance, emphasizing strongly the importance of these actions to ensure the ability of the field to survive.

Every episode of the rigor vs. relevance discussion tends to end with a prediction that the conversation will again lift its head in a few years. This is, indeed, likely to continue to be the case: despite the widely recognized ongoing challenge with relevance and the prescriptive guidance given, little seems to have changed. At the same time, demonstrating the relevance of the field for various stakeholder groups, such as practitioners, students, and public funding sources, has become increasingly important. This is clearly an area where much more work and specific action are needed, particularly if the field desires to be recognized among the practitioners as a source of valuable new practices, fresh ideas, and competent graduates.

1.3.2 Legitimacy and Core of the Discipline

Another very intensive debate within the field of IS has been related to the feeling of anxiety about the legitimacy of the discipline and the associated search for the disciplinary core. Lyytinen and King (2004) provide an excellent concise description of the history of what they call "anxiety discourse," starting from Dearden's (1972) *MIS is a Mirage* and including strongly worded concerns by acknowledged leaders such as Culnan and Huff (1986), Benbasat and Weber (1996), and Straub (1999). Since its beginning, the field has been unsure about itself, to the extent that—paraphrasing Weber—it cannot even agree whether or not it suffers from an identity crisis (Weber, 2003). Lyytinen and King (2004) identify the lack of a strong theoretical core as one possible reason underlying the anxiety (although they do not believe that to be the case). Not surprisingly, there have been many related debates regarding whether or not the field should have a one strong focused core and if it should, what it should be.

The key articles of this conversation and authors' commentaries on their own work a few years later are captured in an important book edited by King and Lyytinen (2006). A comprehensive review of the individual articles or the issues covered in this dialogue is not possible within the scope of this chapter; instead, we will provide a short summary of the key questions and strongly encourage the interested reader to read the King and Lyytinen (2006) book.

One of the key questions debated in this context is whether or not the IS field should have a strong shared identity in the first place. Some very senior scholars within the field have over the years expressed a strong need to identify and articulate the identity of the field so that it can be more unified and defend its legitimacy more easily (e.g., Benbasat and Weber, 1996; Benbasat and Zmud, 2003; Weber, 2006). For example, Benbasat and Weber (1996) very clearly state that "[w]e run the risk, therefore, that diversity will be the miasma that spells the demise of the discipline" (p. 397). Particularly Benbasat and Zmud (2003) led to a number of contributions from other leading academics in the field to defend an opposite perspective that highly values diversity without articulated boundaries (DeSanctis, 2003; Galliers, 2003; Robey, 2003; Ives et al., 2004; see also Robey, 1996; Lyytinen and King, 2006). No true compromise or integrated position has emerged, although seeds of that can be seen already in Benbasat and Weber (1996), who recognize the need for both focusing on the core and achieving diversity around it. According to Taylor et al. (2010), the field has done this by maintaining a "polycentric core" while allowing for a diversity of methods, topics, and research contexts. Whinston and Geng (2004) suggest that allowing "strategic ambiguity" is important to allow continuous innovation within IS research, while still maintaining the centrality of the IT artifact.

Another frequently revisited topic addressed by the most senior members of the IS community is whether or not the field is in crisis. Markus (1999) made an important contribution to this discussion in a book chapter with a provocative title "Thinking the Unthinkable—What Happens if the IS Field as we

Know it Goes Away." Her insightful views regarding the changes needed to the field are still important. Strong concerns regarding enrollments throughout the early 2000s and funding challenges caused by the great recession of 2007–2009 have strengthened the calls for quick action. For example, Hirschheim and Klein (2003) use the question related to the existence of the crisis as a framework to present their own suggestions regarding the state of the field and the direction it should take (interestingly, they end up not taking a stand regarding the existence of the crisis). For Benbasat and Zmud (2003), the crisis is specifically an identity crisis, with potentially very serious effects on the field. Galliers (2003) adopts a very different position, explicitly "deny[ing] that we are at a crossroads in the field" (p. 338). No consensus has emerged regarding this issue, either.

Yet another widely debated topic is the role of the "IT artifact" within the IS discipline. Orlikowski and Iacono (2001) call the IS discipline to engage more deeply in the process of understanding the IT artifact, which they defined as "those bundles of material and cultural properties packaged in some socially recognizable form such as hardware and/or software" (p. 121). After articulating five different views of technology (tool, proxy, ensemble, computational, and nominal), they demonstrate how the great majority of IS articles published in *Information Systems Research* in 1990s are either ignoring the IT artifact entirely or view it from perspectives that hide the significant interdependencies between system characteristics and the social and organizational context in which the systems are used. Orlikowski and Iacono (2001, p. 133) present a beautiful articulation of the special contribution the IS discipline can make at the intersection of technology and the contexts in which it is used, if it takes seriously its role in understanding the IT artifact in a deeper way:

> However, none of these groups attempts to understand the complex and fragmented emergence of IT artifacts, how their computational capabilities and cultural meanings become woven in dense and fragile ways via a variety of different and dynamic practices, how they are shaped by (and shape) social relations, political interests, and local and global contexts, and how ongoing developments in, uses of, and improvisations with them generate significant material, symbolic, institutional, and historical consequences. Yet, this is precisely where the IS field—drawing as it does on multiple disciplines and different types of analyses—is uniquely qualified to offer essential insights and perspectives.

Building on Orlikowski and Iacono (2001), Weber (2003) and Benbasat and Zmud (2003) make a strong call for the centrality of the IT artifact and "its immediate nomological net" (Benbasat and Zmud, 2003, p. 186) within the IS discipline. For Benbasat and Zmud, the IT artifact is "the application of IT to enable or support some task(s) embedded within a structure(s) that itself is embedded within a context(s)" (p. 186) Others, such as Galliers (2003) and DeSanctis (2003), strongly advocate for the need to let the field move without constraints created by the need to link the research to the IT artifact, however it is defined. Recent reviews of the discipline's areas of focus (Sidorova et al., 2008; Taylor et al., 2010) both suggest that in practice, the field continues to embraces a broad perspective without constraints and at best a polycentric core with extensive surrounding diversity.

1.3.3 Reference Disciplines

The final broad discussion topic that the field of IS engages in at regular intervals is that of the relationship between IS and other disciplines, particularly from the perspective of identifying which discipline is serving as a reference discipline to the other. From the early days of the IS discipline, the field has been characterized as one that has its roots in a number of reference disciplines, such as computer science, economics, and psychology (Keen, 1980), management and organization science in addition to computer science (Culnan and Swanson, 1986) or, increasingly, marketing in addition to economics and less computer science (Grover et al., 2006). In the early days of the field, many faculty members had backgrounds in these fields, which (and many others, such as sociology, social psychology, philosophy,

and organizational behavior) also were the source of key theories, conceptual frameworks, and methodological innovations for IS. This continues to be the case (Grover et al., 2006).

The key question more recently has been whether or not IS has reached a status of being a reference discipline itself, contributing to other fields. This is another area where an intense debate appears to continue without a conclusion: some authors (Baskerville and Myers, 2002; Grover et al., 2006) firmly believe that there is strong evidence that IS has emerged as a real reference discipline for related fields whereas others disagree or at least skeptical (e.g., Wade et al., 2006; Gill and Bhattacherjee, 2009). In a recent editorial, Straub (2012) points out that at least one requirement of IS serving as a reference discipline is fulfilled: over its relatively brief history, IS has been able to develop native theories, such as TAM and UTAUT (Section 1.2.1.1 of this chapter), task-technology fit theory (Section 1.2.1.1), adaptive structuration theory (Section 1.2.1.11), and the information success model (Section 1.2.1.6). Regardless of the extent to which IS serves as a reference discipline to other areas of study, the discipline has advanced very significantly from the times when it was solely depending on other fields in terms of its theories and methodologies.

1.4 Summary and Conclusions

This chapter has taken us through the most influential categories of IS research during the past 30 years and a number of ongoing or frequently reemerging scholarly conversations within the field. This last section of the chapter will discuss some of the implications of the findings described earlier.

In Section 1.2.4, the following questions were used to illustrate in practical terms the diverse nature of the most widely cited IS research:

- Why do users choose to accept some technologies readily and others not at all?
- What are the mechanisms through which IT affects organizations and can be used to transform them?
- How do people make decisions regarding communication options using computer-based technologies?
- What structures, incentives, and technologies should organizations have in place to ensure success in knowledge management?
- How do we define and measure the success of IS in organizations?
- Do IT-based solutions really have a measurable impact on business performance?
- What impact do various technologies have on the formation and maintenance of trust in virtual environments?
- What are the special characteristics of electronic marketplaces and how do they operate?
- What are the factors that determine whether or not an individual or an organization adopts an IT solution?

Level of analysis varies from individual to societal, and research methods are equally varied. Philosophically IS researchers view these questions through multiple lenses. The field does not have a shared view regarding whether or not this diversity is good (as indicated in Section 1.3.2). Even if the field came to the conclusion that this diversity should somehow be harnessed, finding practical mechanisms for doing so is difficult (except through very specific editorial policies in our top journals). Still, it is important to keep emphasizing the importance of building cumulative results (Keen, 1980) that will continue to build toward the discipline's own Body of Knowledge.

As discussed earlier, the discipline continues to suffer from an uncertainty regarding its own academic legitimacy and whether or not the field is in crisis. Self-reflective evaluations are important for the development of the field; at the same time, it is essential that an unnecessarily large share of the discipline's top resources is not used on introspective processes. To thrive, the field needs to develop a shared understanding and, indeed, an identity that gives its members a sense of belonging and a basis on which to build the inter- and transdisciplinary collaboration that will be increasingly important.

One surprising result that emerged from the analysis presented in this chapter is the very insignificant role that articles focusing on core IS education topics have among the most influential IS research articles. One can legitimately wonder why research on systems analysis and design, data management, IT infrastructure, enterprise architecture or even IT strategy, management, governance, and acquisition has no visibility among the most highly cited works (together with IS project management, these form the core topics in the latest IS model curriculum, IS 2010; Topi et al., 2010). Maybe even more surprisingly, where are information-related topics? Given the recent emergence of iSchools (sometimes under the informatics title, sometimes information science, or simply information) as serious research enterprises, is the strongest expertise related to information and related topics any more within the field of IS—or has it ever been there? How long can the field make strong claims regarding its true contributions to the practice of IT if its most influential research is very far from these topics?

At the same time, this volume of the Computing Handbook includes a large number of excellent examples of outstanding scholarly work in areas that have been traditionally considered the core in IS (at least in IS education), demonstrating that this work exists and is thriving. It has just not been cited (i.e., used by others) at the same level of intensity as the research that emerged on the top in this analysis. Citations per se are not of importance, but they have an increasingly significant role as a core metric within the research enterprise. In addition, they tell at least a partial story about which research gets noticed and which does not. Also, one has to wonder what these results suggest about the possibilities for integration of research and teaching in the IS field, given that the most highly visible research topics are not aligned with what we teach.

If our focus in education will increasingly move toward general business topics such as, for example, creativity, business process design, service design, or organizational innovation, what differentiates us from other fields within business that have these same interests (such as operations management or marketing)? It appears that Orlikowski and Iacono's (2001) call to move toward a deeper understanding of and stronger theorizing about the IT artifact is as relevant as it was more than a decade ago. Shouldn't IS find its legitimacy and focus in the areas where a true understanding of information and IT is integrated with a true understanding of a domain that wants to benefit from effective and efficient use of information and IT resources? This essential space is there for us to keep and nurture—this is the area that we are uniquely qualified to occupy.

Acknowledgments

I gratefully acknowledge the thoughtful feedback I received from Wendy Lucas, Allen Tucker, and Ryan Wright during the preparation of this chapter. The work on this chapter was made possible by a sabbatical leave and a summer research grant from Bentley University, both of which I also acknowledge with gratitude. Finally, I want to thank Aalto University School of Business for the opportunity to work on this chapter while I was at Aalto as Visiting Scholar and Radford University for a few important days of peace and quiet in the middle of an international move.

Discipline of Information Technology: History and Development

Barry M. Lunt
Brigham Young University

Han Reichgelt
Southern Polytechnic State University

2.1 Introduction

Since the introduction of computers several decades ago, there have always been those who spend some of their time solving problems with computers. This became particularly true after the advent of the personal computer, as in this new era the majority of computer users were not trained in computers, and, indeed, did not want to be. This was intensified as the World Wide Web became ubiquitous. These trends gave rise to the need for professionals with a unique skill set, which, as we will discuss later in this chapter, were not being provided by the traditional computing programs.

In response to these needs, new 4 year computing degree programs emerged at several institutions in the United States; the earliest was introduced in 1992. These programs, which were typically titled "information technology" (IT), grew out of the need to produce professionals with the skills necessary to support the use of the newly ubiquitous computing tools. In the past decade, the number of these programs has grown. In 2012, there are at least 50 such programs, of various flavors, in the United States.

The objectives of this chapter are to further chronicle the emergence of this new computing discipline of IT and its maturation, and to draw a contrast between it and the other computing disciplines.

2.1.1 Emergence of the IT Discipline

The underlying principles of IT have grown out of its history. Historically, those who have worked closely with computers were well educated in computing (starting with those whose academic background is in

the disciplines of computer science (CS) and (IS)). This was also mostly true of those who used computers. And if someone outside the "computing cognoscenti" wanted to use computers, it was necessary for them to immerse themselves in this knowledge domain.

This began to change with the introduction of the personal computer, and with further system software releases (particularly the graphical user interfaces of the Mac OS and Windows). Computers were soon in the hands of people who wanted to harness their capabilities, but did not want to have to learn all the details of how they worked. Thus, the need arose for a computing discipline whose responsibility was to solve computer application problems for this new computing generation. From this history grew the broad goals of IT programs[1]:

1. Explain and apply appropriate information technologies and employ appropriate methodologies to help an individual or organization achieve its goals and objectives
2. Function as a user advocate
3. Manage the IT resources of an individual or organization
4. Anticipate the changing direction of IT and evaluate and communicate the likely utility of new technologies to an individual or organization
5. Understand and, in some cases, contribute to the scientific, mathematical, and theoretical foundations on which information technologies are built
6. Live and work as a contributing, well-rounded member of society

In 2001, several of the institutions with 4 year programs in IT met to formally define IT as a separate academic discipline. The outgrowth of this meeting and the many meetings that followed included a formally accepted model curriculum,[2] accreditation guidelines and criteria,[3] and a special-interest group of the ACM: SIGITE—Special Interest Group for Information Technology Education.[4]

The IT model curriculum, the first draft of which was published in 2005 and which was formally accepted by the Education Council of the ACM in 2008, defines the academic discipline of IT as follows:

> "IT, as an academic discipline, is concerned with issues related to **advocating for users** and meeting their needs within an organizational and societal context through the **selection, creation, application, integration and administration** of computing technologies."[5] (emphasis in original).

This same document further lists the five pillars of IT: programming, networking, human–computer interaction, databases, and web systems, with information assurance and security being a "pervasive theme," which, with other pervasive themes, are "woven-like threads throughout the tapestry of the IT curriculum."[6] The other pervasive themes are as follows:

- User centeredness and advocacy
- The ability to manage complexity through abstraction and modeling, best practices, patterns, standards, and the use of appropriate tools
- Extensive capabilities for problem solving across a range of information and communication
- Technologies and their associated tools
- Adaptability
- Professionalism (lifelong learning, professional development, ethics, responsibility)
- Interpersonal skills

The IT Model Curriculum also points to another important characteristic of the IT discipline, namely, its breadth. As mentioned in the IT model curriculum: "The depth of IT lies in its breadth…,"[7] meaning that an identifying characteristic of the IT discipline is that it is very broad—anything having to do with the applications of computers lies within the domain of IT.

2.1.2 Unique Nature of IT

Until fairly recently, the only computing programs that had had formally defined model curricula were CS, whose first model curriculum was promulgated in 1968, and IS, whose first model curriculum was accepted in 1973. For many years, CS and IS were the only widely recognized computing programs. However, in the early part of the 2000s, the relatively well-established computing disciplines of software engineering (SWE) and computer engineering (CE) started formulating new model curricula, as did the newer computing discipline of IT. These efforts took place primarily under the auspices of the ACM, the Association for Information Systems (AIS), and The Computer Society of the Institute for Electrical and Electronic Engineers (IEEE-CS). It also soon became clear that there was a need to describe the similarities and differences among the different computing disciplines.

In 2003, the ACM invited representatives of all five of these computing disciplines to write a document that would form a guide to undergraduate degree programs in computing. With oversight from the ACM, AIS, and IEEE-CS, two representatives from each of these disciplines met on several occasions. This effort resulted in 2005 in a report entitled "Computing Curricula 2005—The Overview Report." This document became very influential in helping to define the different computing disciplines with respect to each other. It provides, for each of these computing disciplines, insights into their history, descriptions, and graphical views, a table of the comparative weights of computing and non-computing topics (Table 2.1), and a table of the relative performance capabilities of computing graduates.

The Overview Report describes IT in the following way:

> "In the previous section, we said that Information Systems focuses on the information aspects of information technology. Information Technology is the complement of that perspective: its emphasis is on the technology itself more than on the information it conveys. IT is a new and rapidly growing field that started as a grassroots response to the practical, everyday needs of business and other organizations. Today, organizations of every kind are dependent on information technology. They need to have appropriate systems in place. These systems must work properly, be secure, and upgraded, maintained, and replaced as appropriate. Employees throughout an organization require support from IT staff who understand computer systems and their software and are committed to solving whatever computer-related problems they might have. Graduates of information technology programs address these needs.
>
> Degree programs in information technology arose because degree programs in the other computing disciplines were not producing an adequate supply of graduates capable of handling these very real needs. IT programs exist to produce graduates who possess the right combination of knowledge and practical, hands-on expertise to take care of both an organization's information technology infrastructure and the people who use it. IT specialists assume responsibility for selecting hardware and software products appropriate for an organization, integrating those products with organizational needs and infrastructure, and installing, customizing, and maintaining those applications for the organization's computer users. Examples of these responsibilities include the installation of networks; network administration and security; the design of web pages; the development of multimedia resources; the installation of communication components; the oversight of email systems; and the planning and management of the technology lifecycle by which an organization's technology is maintained, upgraded, and replaced."[8]

As indicated in the second paragraph of this quote, the needs of the rapidly growing computing community were not being fully met by the existing computing disciplines in academia. The desire to supply these needs was the major motivating factor that gave rise to the IT programs in academia.

On page 20 of The Overview Report is a depiction of the problem space of computing, specifically depicting the space occupied by IT, as shown in Figure 2.1.

This figure shows that IT is strongly focused on the application, deployment, and configuration of computing systems, and is concerned with four of the five domains identified on the left side of the figure.

TABLE 2.1 Computing and Non-Computing Topics and Performance Capabilities Which Identify IT

Computing Topics
Programming fundamentals
Integrative programming
Operating systems configuration and use
Net centric principles and design
Net centric use and configuration
Platform technologies
Human–computer interaction
Information management (DB) practice
Legal/professional/ethics/society
Analysis of technical requirements
Security: implementation and management
Systems administration
Systems integration
Digital media development
Technical support
Non-computing topics
Risk management (project, safety risk)
Mathematical foundations
Interpersonal communications
Performance capabilities
Provide training and support for users of productivity tools
Create a software user interface
Train users to use information systems
Maintain and modify information systems
Model and design a database
Select database products
Configure database products
Manage databases
Train and support database users
Develop computer resource plan
Schedule/budget resource upgrades
Install/upgrade computers
Install/upgrade computer software
Design network configuration
Select network components
Install computer network
Manage computer networks
Manage communication resources
Manage mobile computing resources
Manage an organization's web presence
Configure and integrate e-commerce software
Develop multimedia solutions
Configure and integrate e-learning systems
Evaluate new forms of search engine

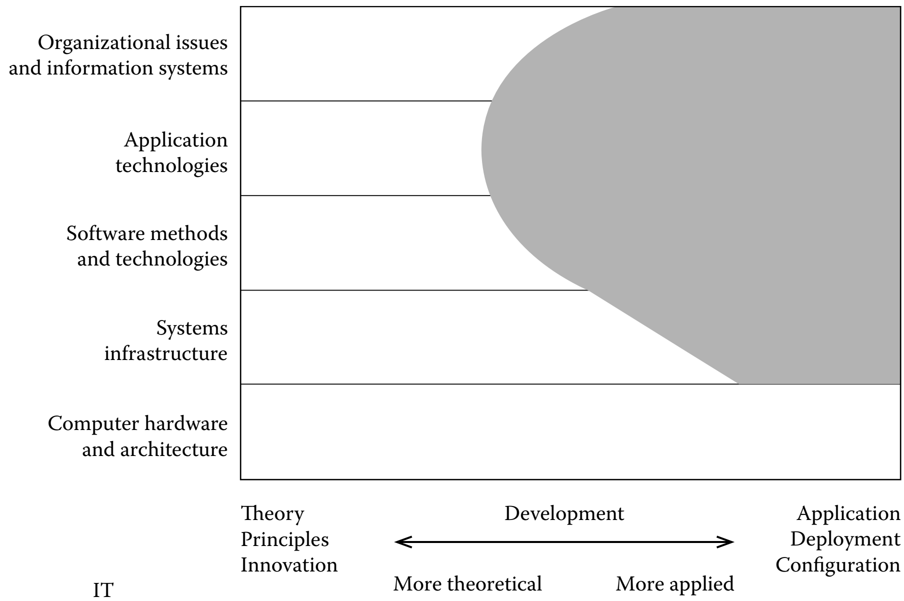

FIGURE 2.1 The problem space occupied by IT. (From p. 20 of The Overview Report, The Joint Task Force for Computing Curricula 2005, a cooperative project of ACM, AIS, IEEE-CS, http://www.acm.org/education/education/curric_vols/CC2005-March06Final.pdf)

It should be noted that since this figure was created and the field has matured, IT has developed a stronger focus in the area of systems infrastructure, which would be depicted in this figure by extending to the left the area of the gray shape in that fourth domain. For example, the IT model curriculum, which was still in draft form when the Overview Volume was being formulated and which was formally accepted in 2008, contains 10 IT-specific knowledge areas, of which four (platform technologies, networking, system integration and architecture, and system administration and maintenance) are most directly concerned with the systems infrastructure and one (information assurance and security) has a direct bearing on this layer.

Commenting on the information depicted in Figure 2.1, and similar figures for CE, CS, IS, and SWE, Agresti,[9] in his 2011 paper, points out that these figures give each of the disciplines a "disciplinary theme," and these themes are:

CE = Hardware
CS = Theory
IS = Organizations
IT = Deployment
SE = Development

In explaining his choice of "deployment" for the IT disciplinary theme, Agresti states:

> "[The figures depicting computing space] portray IT as anchored in the world of deployment, structuring and configuring computing artifacts. As new technologies appear, they need to be integrated with existing systems to have any beneficial effect for users." (p. 260)

Thus, one of the main underlying principles of IT is that students in this discipline, compared to the other computing disciplines, should be the broadest in their knowledge of computing. They should know how to work with people of any discipline who know practically nothing about computers. They should know how to speak the language of those who do not care (or need) to know the details of how computers work or how to fix them. They should know how to get disparate computing systems to

work together. They should be very knowledgeable about each of the IT pillars of databases, human–computer interaction, networking, programming and web systems, and the pervasive themes from the IT model curriculum. The depth of this discipline is not in a single or a few knowledge areas, but in the breadth required. This goes along well with Agresti's comment:

> "Integration of technologies and interactions among them should be major focus areas of the IT discipline."[10]

Another insight provided in this Overview Report is the data summarized in Table 2.1, consisting of the computing topics, non-computing topics, and relative performance capabilities of graduates of IT programs. In this table, the only topics or capabilities included are those for which IT programs were rated at a 4 or a 5 (out of 5), meaning that IT programs considered them an essential part of the identity of IT.[11]

2.1.3 Accreditation

In 2003, SIGITE produced the criteria by which IT programs could be accredited by the Computing Accreditation Commission (CAC) of ABET. These criteria were accepted by CSAB Inc. and ABET in 2004, and in 2005 ABET began accrediting IT programs, along with programs in other major computing disciplines which ABET had already been accrediting.

At the time the IT criteria were created, the IT discipline was the only one of the three disciplines accredited by ABET CAC that had adopted an outcome-based approach to accreditation criteria.

TABLE 2.2 Program Criteria for Information Technology and Similarly Named Computing Programs

Student Outcomes

a. An ability to apply knowledge of computing and mathematics appropriate to the discipline
b. An ability to analyze a problem, and identify and define the computing requirements appropriate to its solution
c. An ability to design, implement, and evaluate a computer-based system, process, component, or program to meet desired needs
d. An ability to function effectively on teams to accomplish a common goal
e. An understanding of professional, ethical, legal, security, and social issues and responsibilities
f. An ability to communicate effectively with a range of audiences
g. An ability to analyze the local and global impact of computing on individuals, organizations, and society
h. Recognition of the need for and an ability to engage in continuing professional development
i. An ability to use current techniques, skills, and tools necessary for computing practice
j. *An ability to use and apply current technical concepts and practices in the core information technologies
k. *An ability to identify and analyze user needs and take them into account in the selection, creation, evaluation and administration of computer-based systems
l. *An ability to effectively integrate IT-based solutions into the user environment
m. *An understanding of best practices and standards and their application
n. *An ability to assist in the creation of an effective project plan

Curriculum

1. Coverage of the fundamentals of
   a. The core information technologies of human–computer interaction, information management, programming, networking, web systems, and technologies
   b. Information assurance and security
   c. System administration and maintenance
   d. System integration and architecture
2. Advanced course work that builds on the fundamental course work to provide depth

The outcomes preceded with an * are those which are uniquely associated with IT programs.

TABLE 2.3 Universities with IT Programs Accredited by CAC of ABET, as of February 2012, Ordered Alphabetically

Academic Institution	Location
Brigham Young University	Provo, UT
Capella University	Minneapolis, MN
Drexel University	Philadelphia, PA
East Tennessee State University	Johnson City, TN
George Mason University	Fairfax, VA
Georgia Southern University	Statesboro, GA
Indiana University-Purdue University Indianapolis	Indianapolis, IN
Macon State College	Macon, GA
Purdue University at West Lafayette	West Lafayette, IN
Rochester Institute of Technology	Rochester, NY
Slippery Rock University	Slippery Rock, PA
Southern Polytechnic State University	Marietta, GA
United States Military Academy	West Point, NY
United States Naval Academy	Annapolis, MD
University of Cincinnati	Cincinnati, OH
University of Missouri-Kansas City	Kansas City, MO
University of North Florida	Jacksonville, FL
University of South Alabama	Mobile, AL

In other words, IT was the first of the three computing disciplines that formulated its criteria primarily in terms of the skills and knowledge that graduates from accredited IT programs could expect to have acquired, rather than in terms of, for example, the courses students needed to complete. This was probably a direct consequence of the fact that ABET itself had moved to an outcome-based approach shortly before the IT community formulated its accreditation criteria.

However, with ABET's greater emphasis on outcomes, CS and IS also reformulated their criteria in terms of outcomes. Moreover, since ABET CAC wanted to be able to accredit computing programs that were not necessarily named "CS," "IT," or "IS," the criteria were divided into general criteria, which any program in computing must meet to be accreditable, and program-specific criteria for specific computing disciplines. As part of this effort, a distinction was made between attributes that any graduate from a computing program should possess, and those attributes that are specific to graduates from IT programs. Table 2.2 lists the attributes for IT. Today there are 18 IT programs which have been accredited by the CAC, as shown in Table 2.3.

2.2 Distinguishing Characteristics of the IT Discipline

Because of the emergence of the computing discipline in response to a workforce development need, it can be argued that one of the distinguishing characteristics of IT is its highly practical nature. Computing has permeated a myriad of activities and disciplines, and graduates from IT programs are expected to be able to support computing tools and their users in a variety of settings. Because of this, most IT programs have an expectation that students develop some knowledge of a particular application domains, be it geology, health care, crime investigation, archeology, entomology, etc.

A good example of this is provided by the IT program at Georgia Southern University that originally required all IT students to include a so-called second discipline in their program of study, essentially a directed minor, with the explicit aim of making sure that students developed sufficient knowledge of an application domain to be able to develop and support IT applications for that domain.[1] As a result,

the main impact that IT has on practice lies in the application domains where it is deployed, and upon which each domain has become increasingly dependent. A few examples will help make the point.

2.2.1 Applications in Health Care

All health-care providers have the need to have access to accurate and current patient records. These records should be secure, convenient, thorough, and readily available wherever they or their patients may be. This is an IT issue.

Drugs for health care must constantly be under inventory control, to keep supplies adequate for needs and to monitor for theft or abuse. The supply chain for these drugs must be documented to assure their authenticity and purity. Much of this is an IT issue.

Over the past few decades, billions of patient health-care records have been kept on computers. Such records often include data such as the demographics of the patient, the symptoms they experienced, the treatments provided, and the results of the treatments. This information, if fully searchable, constitutes a vast database which could yield dramatic insights into health-care treatments and their effectiveness. Making such a database readily available across all platforms (the Internet, desktops, laptops, tablets, and smart phones) is another research area with a large IT component.

2.2.2 Applications in Law Enforcement

Perpetrators usually have a characteristic method of operation (MO), which can often be used to recognize a group of crimes which may have all been committed by the same person. If there were a readily accessible and secure database which could be easily searched by law-enforcement workers, it would greatly enhance their ability to solve crimes. There has been a lot of progress in this area, and this progress is sufficient to convince practically anyone that further effort in this direction will yield great improvements. Such a database would be even more valuable if it were worldwide and available across all platforms. Since the Internet is nearly ubiquitous, it is probably only a matter of time and effort before this can be accomplished. Much of the wide deployment of this crime database is an IT issue.

Each person who has a criminal record has specific conditions of their position, whether incarcerated, on parole, in a half-way house, or free. Law-enforcement officers are greatly aided when they are quickly able to determine what these conditions are for each individual. Much of this is an IT problem.

Crime-scene investigators are greatly aided by rapid analysis of forensic evidence. And today, much of that evidence is digital, including cell-phone records and contents, laptop and pad-type computers, and GPS records. Accessing this evidence and amalgamating it with all the other crime-scene evidence is largely an IT issue.

2.2.3 Applications in Manufacturing

Manufacturing of a typical integrated circuit (IC) involves approximately 500 steps, each of which must be precisely controlled in the materials used, the temperature, the pressure, the time, and other parameters, which together are the "recipe" for each step and for each type of IC being produced. If any of these ingredients or conditions in any step of the recipe is not exactly controlled, or if any of the 500 steps is performed in the wrong order, hundreds or even thousands of ICs will be faulty and would have to be scrapped. Solutions in this domain always involve people from varied backgrounds, needing to access multiple data sources and integrate multiple applications. Thus, a very significant need is to have professionals able to work in nearly all areas of computing. These are IT professionals.

For most products today, each step in the manufacturing process is carefully monitored and data are gathered. These data, as with health-care and law-enforcement databases, become a rich store of data which can be mined to find ways to improve the manufacturing process. Much of this is an IT problem.

2.2.4 Applications in Education

Only a few decades ago, students registered for college classes with pen-and-paper forms which they took around to classes and had their professors sign. Problems and conflicts were many, especially in classes for which the demand was particularly high. Today, students at most institutions of higher education can register based on their class standing (with graduate students getting first pick, then seniors, juniors, etc.). They can see how many openings there are in every class they wish to register for. And they can do it all from their mobile platform of choice or a fixed computer. This dramatic improvement in the registration process has been primarily an IT solution because it has involved the integration of databases, hardware, networks, human–computer interfaces, web systems, security, storage, applications, and integrative programming.

College professors today have access to a very wide array of materials, including video clips, audio clips, photos, simulations, questionnaires, forms, equations, and applications. Many of these are available on the Internet. But there are concerns with copyrights, licenses, controlling access, and availability. At many institutions of higher education, such materials are made available through "courseware," which is basically software that pulls together solutions for appropriate delivery of all such materials. This has greatly enriched the educational experience for all teachers and students with such access. Applying such courseware across an institution and all its varied courses is primarily an IT issue for the same reason as mentioned in the previous paragraph—because it involves the integration of so many computing areas and is deeply technical.

2.2.5 Summary: Impact on Practice

The preceding examples are illustrative only; many more examples could be provided in dozens of application domains. Graduates from computing disciplines such as CS and SE have done much to produce software for these applications. Graduates from CE have done much to provide hardware specific for these domains. And graduates from IS have done much to define how the software and hardware must perform in their specific organization and how information is processed to benefit the organization. And when the software and hardware are both deployed, there are always some changes that need to be made to make the system more effective in specific applications—that is the part most often played by the IT professionals. They must be able to see the entire situation as a system, consisting of multiple entities, each of which must be understood, and their interactions also known and designed for. In each of the scenarios described previously, the unique contribution provided by IT professionals is their view of the system as a whole. Thus IT professionals must be broad, able to deal with problems in the infrastructure, the software, the hardware, the networking, the web, the database, the human–computer interaction, the security, or any other part of the computing system.

2.3 IT Literature

The more practice-oriented nature of IT is also reflected in its relationship to the so-called practitioner literature, including white papers and case studies (some published by consulting firms), and the articles that appear in more practice-oriented publications, such as *Educause Review* and *CIO Magazine*. This material often reflects valuable insights from practice, but lacks the scientific rigor that is typically demanded by academic researchers. At the same time, the practitioner literature tends to have a greater influence on practice than the academic literature and since IT programs strongly prepare their students for practice, the discipline has to pay greater attention to this literature than some of the other computing disciplines do.

A good example that illustrates this is the emergence of the IT Infrastructure Library (ITIL), a set of best practices for IT service delivery. While there is relatively little academic literature on ITIL, the practitioner literature is replete with examples of implementations of ITIL and claims about its ability to improve the quality of IT service delivery. IT service organizations are starting to widely adopt the ITIL framework. As a reaction to this trend, IT programs are therefore starting to include coverage of ITIL.[12]

As Reichgelt et al. (Chapter 4 in this volume) argue, the fact that the practitioner literature lacks the rigor demanded by academia opens up a viable stream of possible research topics for the academic IT

community, namely, projects to find solid evidence for the claims made by practitioners using the traditional methods used in the various computing disciplines.

2.4 Research Issues

This volume contains a chapter on the topic of research in IT (see Chapter 4); the reader is advised to study that chapter for further depth in this area.

The academic discipline of IT is centered on the scholarship of application and the scholarship of integration, as defined in Boyer.[13] This means that research in IT is most likely to be concerned with applications of IT in solving problems in many fields of endeavor. A bottom-up study of IT research embodied in IT masters theses[14] shows that of the 70 theses studied, they could be classified into 5 categories:

1. Development projects (case studies)
2. Education and IT for the education domain
3. Information assurance, security, and forensics
4. Project management and IT for the project management domain
5. Technology evaluation and modeling

Subsequent research[15,16] has reinforced these categories. Taken together, these categories demonstrate the point that IT is focused on application and integration. It is important to recall that the third category embraces the most central of the IT pervasive themes, which further emphasizes the point that the domain of IT is best defined by application and integration.

2.5 Future of Information Technology

There are two trends that are likely to influence the further evolution of the discipline of IT.

The first is that we are likely to see further growth in IT programs around the world. For example, the shift toward cloud computing in the way information services are delivered will result in a growing number of data centers, a trend that is likely to be exacerbated by the continued growth in the use of computing to support organizations and individuals. There will therefore be a growing need for graduates with the type of skills instilled by IT programs.

The growth of IT is likely to manifest itself in three ways. First, it is likely that there will be more programs calling themselves "IT" emerging at more institutions. However, there is also a second, more subtle, way in which IT is likely to become more widespread, in that programs will emerge that may not call themselves "IT" but that cover a large part of the IT model curriculum. Examples might include programs in information security or network technologies. Third, there is likely to be a shift in existing computing programs toward a greater coverage of aspects of the IT model curriculum. For example, more and more CS programs are introducing courses on information security that place a much greater emphasis on the more practical way in which these topics are covered in the IT model curriculum than the more theoretical way in which related topics are covered in the CS model curriculum. For example, such courses place much less emphasis on encryption algorithms and more emphasis on the more practical aspects of hardening the IT infrastructure against attacks.

All of this raises the question of how an IT program is defined. Rowe et al. have developed a series of metrics based on the IT model curriculum to determine how close a program is to being an IT program, independently of how it decides to designate itself.[17] Using this metric, over 900 BS programs in computing in the United States were evaluated and over 300 of these programs were scored using these metrics. The results of this analysis produced a list of 4 year IT programs in the United States, as well as a list of names by which these programs call themselves.[18] The point of this is that there is a great deal of diversity in computing programs, and in programs that appear to be IT programs. It is very likely that this diversity will continue to increase, as it seems to have done over the past few decades.

A second likely development is the greater emphasis on research. There is a growing realization within the academic IT community that if IT is to thrive, it needs to gain more credibility as a serious academic discipline. This is especially important in light of the fact that high-quality IT programs typically rely on more expensive equipment than, say, CS, IS, or SWE. For example, given the growing importance of cloud computing, and given the need to allow students to develop knowledge and skills of the type of data centers that support cloud computing, IT programs may wish to build scaled-down versions of such data centers. However, even scaled-down data centers are considerably more expensive than the more traditional computing labs to support programs in the other computing disciplines, and, at a time where resources are scarce in academia, it is often to make the case for a discipline that lacks academic credibility.

As an example, SIGITE, the ACM Special Interest Group for IT Education and an organization heavily involved in the formulation of both the IT model curriculum and the ABET CAC accreditation criteria for IT, has recently expanded its annual conference to include a joint conference on Research in Information Technology (RIIT). We are also seeing a growing number of papers calling for the need for an IT research agenda (see, e.g., [13], or the chapter by Reichgelt et al. in this volume).

The greater emphasis on research is also likely to result in a greater number of graduate programs in IT. An interesting issue that is likely to arise in this context is whether the traditional PhD program, with its much greater emphasis on theory, is best for IT, or whether the more professionally focused doctoral programs, such as Ed.D (Doctorate of Education) or DBA (Doctorate of Business Administration) programs provide a more appropriate model.

2.6 Summary

IT is both a very broad term and a much narrower term. The broad meaning of IT is anything having to do with computers. The much narrower meaning is the academic discipline of IT, which first arose in about 1992, and which was formally defined starting in 2003 and ending in 2008. As an academic discipline in computing, it has now taken its place alongside the CS and IS veterans and the CE and SE relative newcomers.

IT is primarily focused on integration and system-type thinking in computing. Its purview includes anything in computing, but it is generally not deep in any single domain of computing. IT prepares computing generalists, whose job includes the selection, application, creation, integration, and administration of computing solutions for an organization.

IT has accreditation criteria which have been used by ABET to accredit 18 4 year IT programs in the United States. IT also has a model curriculum which is of great value to any institution looking to establish or modify an IT program. There are at least 50 4 year IT programs in the United States today, and that number appears to be growing.

Glossary

Forensics: For IT, this term refers to the efforts necessary to preserve evidence found in all types of IT artifacts, including phones, computers of all kinds, flash memory, optical disks, hard-disk drives, and magnetic tape. This also includes analyzing, recovering, identifying, and presenting summary information of the evidence found.

Information assurance and security: This field is known by at least three terms: information assurance; security; and cybersecurity. In this document, we have chosen to use information assurance and security for this field, as is done in the IT model curriculum.

Model curriculum: Each of the five major computing disciplines has defined a model curriculum (see http://www.acm.org/education/curricula-recommendations). This formally defined and approved document represents the best thinking of professionals in IT education and describes the core of what a 4-year program in IT should include.

Further Information

Reference #1, cited several times, is definitive and should be consulted for further information. For comparing the various computing programs with formally defined model curricula, the reader should consult reference #8, which is also definitive in that regard.

3

Information Systems as a Practical Discipline

Juhani Iivari
University of Oulu

3.1 Introduction

The purpose of this chapter is to discuss information systems (IS) as a practical discipline or science, "which is conceived in order to make possible, to improve, and to correct a definite kind of extra-scientific praxis" (Strasser 1985, p. 59). Referring to Hassan (2011) but contrary to Strasser (1985), this chapter prefers to speak about a discipline rather than a science in the context of IS.

The practical relevance of disciplines is often discussed as a dilemma between relevance and rigor (Keen 1991, Benbasat and Zmud 1999). A dilemma more specific to IS is how to ensure its practical relevance without condescending into commercial faddism. Much of the IS research agenda still continues to be determined by consultants and gurus, and various fads are part of our scientific language (Baskerville and Myers 2009). Following the commercial culture of the fashion setters, many IS researchers tend to introduce each hype as a radical or disruptive innovation, instead of seeking invariants and continuities between ideas and technologies.

Partly because of this commercial faddism, it is hard to see a greater cumulative tradition in IS research than 25 years ago when Banville and Landry (1989) characterized it as a "fragmented adhocracy." Due to the technological development, IS research problems and topics have continued to proliferate, theoretical frameworks applied have become more numerous and diverse, and research methods more pluralistic. Precisely because of these factors, IS researchers should, however, resist the temptation to artificially reinforce and amplify fashion waves.

Benbasat and Zmud (2003) attempted to bring some order into this fragmentation. According to them, the core of IS is determined by the information technology (IT) artifact and its immediate nomological net. They discuss their proposal in terms of errors of exclusion and errors of inclusion in IS research. Errors of exclusion refer to studies that do not include the IT artifact or elements of its immediate nomological net. Errors of inclusion, on the other hand, refer to studies that include non-IT constructs—that is, those not included in the nomological net—especially if they are causally distant from those of the nomological net.

Their proposal has received exceptional attention and also severe criticism (see Agarwal and Lucas 2005, King and Lyytinen 2006), much from the viewpoint of the academic legitimacy of IS. The academic legitimacy of IS is hardly a serious problem, at least in Scandinavia or elsewhere in Europe, and according to Mason (2006) not even in North America. Thus, this point of criticism is not very relevant, although Benbasat and Zmud (2003) themselves raise the legitimacy issue as a major motivation for their proposal.

On the contrary, the thesis of the present chapter is that the intellectual core of IS is crucial for the practical relevance. Because of errors of exclusion, IS research has suffered from a weak attention to the IT artifact (Orlikowski and Iacono 2001). Theories are mainly borrowed from reference disciplines. These theories are often totally void of any IT-specific substance. All this has likely diminished the practical relevance of IS research.

Furthermore, the present chapter is based on the conviction that seeking invariants and continuities between ideas and technologies is a more effective way of ensuring the practical relevance of IS than adhering to commercial faddism. There are a number of reasons for this. First, there is no point competing with consultants and gurus by just emulating their behavior. Second, helping practitioners to understand that a new fad is a mutated version of an older idea or just old wine in a new bottle helps them to make better sense of the fad in question. Third, a better understanding of predecessors makes it possible to transfer knowledge and experience from the past and possibly to avoid repeating mistakes. All these can be expected to increase the credibility of IS research at least in the longer run.

The structure of this chapter is as follows. The next section defines the territory of IS among the disciplines of computing, suggesting that the special focus of IS lies on IT applications rather than on IT artifacts in general. After it, the external praxes or practices to be supported by IS research are discussed, identifying three major areas—IT management, IT application development, and IT application usage. Focusing on IT application development, the following section suggests a three-tier model that includes design by vendor, design by client collective, and design by users. Continuing to focus on design, the question of how IS research can effectively support the identified external practices is discussed next. The section suggests that IS research should focus on actionable and, more specifically, on designable qualities of IT applications so that the research outcomes can inform design at different stages of design in the three-tier model. Finally, the implications of the article are discussed.

3.2 IT Artifacts and IT Applications

All disciplines of computing—computer engineering, computer science, software engineering, IT, and IS (Shackelford et al. 2005)—are interested in IT artifacts. IT artifacts form the *raison d'être* of their existence. This common interest in IT artifacts makes disciplines of computing—especially the last three of them—sister disciplines. There is a considerable overlap between them especially at the level of base technologies such as data communication, software, databases, and user interfaces, as well as in the case of system development methods, techniques, and tools.

Iivari (2007) suggests that the distinctive focus of IS among disciplines of computing lies in IT applications rather in IT artifacts in general. As a consequence, IS can be conceived as a discipline of computing that specifically focuses on IT applications, on their development, use, and impact at individual, group, organizational, community, society, and global levels.

IT applications are IT artifacts that have human beings as users and have functionality/capability to produce direct services to their users.* The concept of IT application is close to "application software," but not exactly the same. First, an IT application does not comprise only software but also the physical device(s) required for the operation and use of the system. Second, it may also include content that is not software by nature (e.g., information content). Third, an IT application may be an instantiation

* The word "direct" attempts to exclude so-called systems software from the category of IT applications. The services provided by systems software are indirect in the sense that they are required for providing the services of IT applications.

TABLE 3.1 Ideal Types of IT Applications

Intended Purpose	Examples
To automate	Many embedded systems
	Many transaction processing systems
To augment	Many personal productivity tools, computer-aided design tools
To mediate	Computer-mediated communication (CMC): Internet phone calls, e-mail, instant messaging, chat rooms, etc.
To informate	Information systems (proper)
To entertain	Computer games (Aarseth 2001, Davis et al. 2009)
To artisticize[a]	Computer art (Noll 1995, Edmonds et al. 2004, Oates 2006)
To accompany	Digital (virtual and robotic) pets (Kusahara 2001, Friedman et al. 2003)
To fantasize	Digital fantasy world applications (Davis et al. 2009)

[a] The word "artisticize" is introduced to refer to subjecting a person to an artistic experience as a consumer or possibly also as an interactive creator of a piece of (computer) art.

of application software (e.g., an enterprise resource planning (ERP)-based information system is an instantiation of ERP software, but ERP software is not an application as itself).

Iivari (2007) also introduces an open-ended typology of IT applications that, in its current version, includes eight types depicted in Table 3.1. The proposed typology is not based on any reference theory. Instead it is a Type I theory in the framework of Gregor (2006)—"theory for analysing" that is specific to IT applications, based on the analysis of their major purposes.

The first four archetypes are close to "technology as a labor substitution tool," "technology as a productivity tool," "technology as a social relations tool," and "technology as an information processing tool" in Orlikowski and Iacono (2001). So, essentially Table 3.1 extends Orlikowski and Iacono (2001) by introducing four additional types. Computer games illustrate the capability of IT applications to entertain. IT applications may also attempt to arouse artistic experience, and one can easily imagine a new sort of art that is essentially built on the dynamic and interactive character of computer technology. IT artifacts such as digital pets can accompany human users. Finally, computers allow users to build digital fantasy worlds and have fantasy-like experiences. Table 3.1 identifies some references to these non-traditional application types.

As ideal types, the IT applications of Table 3.1 may not occur in their pure forms in practice, but one can identify examples that are close to them. Yet, many real IT applications are combinations of the ideal types for several reasons. First, a single IT application may be deliberately designed to include several purposes in terms of Table 3.1. For example, an information system (proper) may be designed to include game features to motivate the use of the system and to support learning in the case of educational IS as exemplified by Age of Empires II: The Age of Kings (http://www.microsoft.com/games/age2/). Second, an IT application of one archetype may include auxiliary functions of another archetype to support of the use of the system. For example, e-mail with the original function of communicating messages includes mailboxes that allow one to build a directory to informate about previous communications. Thus, it can be developed into a fairly sophisticated information system about one's electronically mediated social network and one's electronic communication within that network. Third, Zuboff (1988) claimed that to automate also allows one to informate. This can obviously be extended to cover other uses of IT applications, so that computer games, for example, could at least in principle collect information about their use and about users' actions and reactions during playing. A final point is that applications of one archetype can be used to implement applications of another archetype. For example, spreadsheet software as an augmenting tool can be used to implement a specific information system.

Referring to the proliferation of IT applications, one should note that a sound typology of ideal types also enables to address this increased variety of IT applications. The eight ideal types alone can be

combined in 255 ways. If one adds different application domains (e.g., business, government, healthcare, education, library, and geography), one could have thousands of different application types just in terms of the eight ideal types. It is this variety of IT applications that makes the ideal types significant. Recognizing that many practical IT applications are combinations of ideal types, research can focus on much fewer ideal types, assuming that a deeper understanding of ideal types—their similarities and differences within and across application domains—also informs about the hybrid applications in different application domains.

Related to fashion waves, the first question to be asked in the case of each new (type of) IT application is whether or not it really is so new that it does not have any predecessors and cannot be viewed as a subset or an instance of a more general type of IT applications of Table 3.1. Because IT applications represent artificial reality, it may well be that fundamentally new IT applications will be invented that cannot be interpreted in terms of the eight archetypes of Table 3.1. That is why the typology of Table 3.1 is open-ended. Yet, situations like this are likely quite rare events.

If one accepts that IS is a discipline of computing that specifically focuses on IT applications in Table 3.1, it is clear that the territory of IS goes beyond the workplace use of utilitarian IT artifacts. Although non-utilitarian use is occasionally recognized in the IS literature (e.g., Davis et al. 2009, Lin and Bhattacherjee 2010), much of IS research still continues to assume utilitarian use in the workplace (e.g., Benbasat and Zmud 2003, Benbasat and Zmud 2006, Burton-Jones and Straub 2006, Barki et al. 2007).

3.3 External Practices to Be Supported by IS Research

The idea of IS as a practical discipline leads to the need to identify those practices that IS attempts to enable, to improve, and to correct. One can distinguish three interacting focus areas with associated actor groups depicted in Figure 3.1.*

Among three subfields of IT management—IT project management, management of IT function, and IT governance—the last one is introduced to emphasize three points.† First, it can be practiced at the national, regional, and global levels in addition to the organizational level as normally assumed. Second, IT governance is exercised by actors external to IT such as senior management in organizations, top government officials, and political leaders at the national, regional, and global levels. Third, IT governance practiced by these external actors points out that the core of IS should not be interpreted as exclusive. If IS researchers are able to inform these decision-makers in the issues of IT governance, the relevance of their work is likely very high, even though may include some errors of inclusion.

The three subfields of IT application usage are inspired by Barki et al. (2007), who distinguish three behaviors—technology interaction behaviors, task-technology adaptation behaviors, and individual adaptation behaviors—in the case of individual usage. The idea of Figure 3.1 is, however, that IT application usage can be viewed at different levels such as individuals, groups, organizations, communities, and societies. Therefore, the three behaviors suggested by Barki et al. (2007) are renamed aiming at more generality, pointing out that in addition to IT application use, the application may be redesigned in the adopting unit while used, and also the adopting unit may adapt or be adapted to reflect the IT application and its use.

Figure 3.1 identifies three subfields of IT application development: design, implementation, and evaluation. Design is here interpreted to cover also analysis activities needed in design. IS implementation refers to the process of adoption, appropriation, acceptance, instantiation, and/or institutionalization of the designed IT application in the adopting unit in question. Adapting Ammenwerth et al. (2004),

* The actor groups in Figure 3.1 may be interested in several areas, but for simplicity they are associated with one.

† IT Governance Institute (ITGI 2003, p. 10) defines IT governance as "the responsibility of the board of directors and executive management. It is an integral part of enterprise governance and consists of the leadership and organizational structures and processes which ensure that the organization's IT sustains and extends the organization's strategy and objectives."

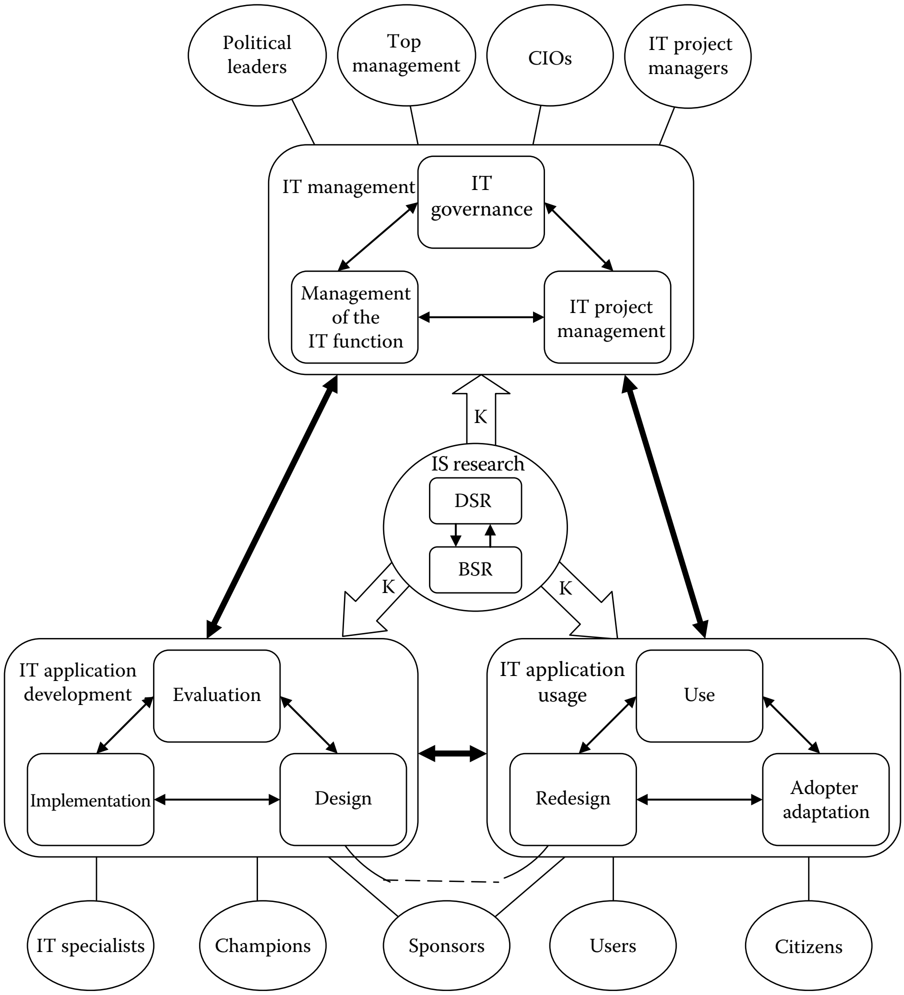

FIGURE 3.1 Extra-scientific practices supported by IS research.

evaluation is interpreted here as an act of measuring or exploring qualities (such as worth, value, benefits, cost, and impact) of an IT application and the related changes, the result of which informs a decision to be made concerning that application in a specific context. Evaluation studies in health informatics (Kaplan and Shaw 2004) illustrate the potential of evaluation studies to inform the practice. General IS research has also a similar potential, if IT constructs are incorporated more strongly in behavioral science research (BSR) models—as implied by the nomological net of Benbasat and Zmud (2003). In that case much of descriptive BSR would actually evaluate IT applications or types of IT application.

The dotted arrow in Figure 3.1 reminds that depending on the perspective redesign during usage may be viewed as a part of IT application usage and a part of design activity in IT application development. The following section elaborates this by distinguishing a three-tier model of IT application design.

3.4 A Three-Tier Model of IT Application Design

Benbasat and Zmud (2003, p. 191) claim that "our focus should be on how to best design IT artifacts and IS systems to increase their compatibility, usefulness, and ease of use or on how to best manage and support IT or IT-enabled business initiatives." If one accepts this view, design of IT applications is a key

activity to be supported by IS research. Still, research on systems analysis and design is underrepresented especially in mainstream IS research (Vessey et al. 2002, Bajaj et al. 2005).

Furthermore, IS research has largely focused on the in-house IS development (Light and Sawyer 2007). However, much of IS development has, almost from the beginning of the field, been based on prefabricated application software provided by vendors. This software covers application packages (e.g., Gross and Ginzberg 1984, Iivari 1986/1990, Lucas et al. 1988), ERP software within the previous category (e.g., Davenport 1998, Pereira 1999), business components in the component-based software development (e.g., Fellner and Turowski 2000, Vitharana et al. 2004), and software services at different levels of granularity. The units of software services may be complete IS applications as provided by software service bureaus at first and application service providers later (Tebboune 2003) or more granulated units of service to be assembled into applications (Elfatatry 2007, Papazoglou et al. 2007). In the case of other types of IT application, the vendor role tends to be even more prominent, since they are typically acquired by clients as packaged applications (such as text processing), as parts of software-intensive products (e.g., vehicular control software), or accessed as services (e.g., social networking websites).

As a consequence, the design of IT applications has become more distributed not only geographically but also temporarily in the sense that the initial design of the application is often done by a vendor and the design may be continued by a client collective and by individual users.* The term “collective” is used here to refer to a group, organization, or community, in association with which a user—as a member, as an employee, as a customer, etc.—makes usage of the IT application in question. The software provided by the vendor may be commercial (e.g., MS Office) or free (e.g., Open Office). Let’s explore an example of application packages such as ERP suites. The software provided by an ERP vendor is supposed to be configured by a specific organization. Although not normally recommended, the client may also customize the system. Finally, the resultant ERP-based IS application may be personalized by the user. This leads to the model of Figure 3.2.

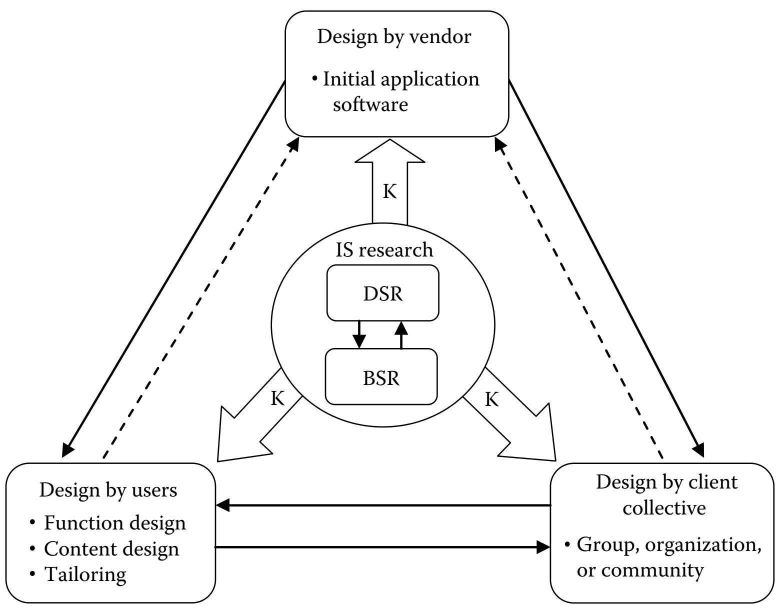

FIGURE 3.2 A three-tier model of IT application design.

* In each case there may be agents involved. The vendor may use contractors, the collective may have outsourced part of its software design, and the user may use technical experts to help. The present article does not delve into this complication.

Design by users in Figure 3.2 corresponds to "secondary design" in Germonprez et al. (2011) who discuss it at the functional layer and at the content layer. Figure 3.2 also includes tailoring by users as a third example, since "secondary design" does not necessarily concern the functionality of the system or its content, but may be limited to the redesign of the user interface, for example.

Figure 3.2 expands the distinction between primary design and secondary design in Germonprez et al. (2011) into a three-tier model. Design between users and design by client collective do not assume a predefined order, but can proceed either way or interactively. For example, a collective such as an organization may design a standard for web pages of its employees and after that employees are assumed to design their web pages so that they comply with the standard. On the other hand, a group or community may design its web pages bottom-up so that members design their web pages first and after that they are linked together to form the group's website.

From the viewpoint of the practical relevance of IS the three-tier model is significant in two respects. First, if IS research wishes to influence the quality of IT applications in practice, it is pivotal to pay attention to the initial design of those applications by vendors. It is obvious that the quality of this initial design significantly determines the quality of the final IT application, after possible configuration, customization, and user tailoring. Second, all this implies that we should pay much more attention to the vendor side in addition to the client side and user side as is traditionally done, although a better understanding of the latter ones may inform the vendor side, too.

3.5 How Can Information Systems Support Practice?

Figure 3.1 as well as Figure 3.2 assume that IS research—whether following the BSR orientation or the design science research (DSR) orientation—may enable, improve, or correct the related practices by providing relevant knowledge (K). This is the case also in the context of DSR, since the essence of IT artifacts as DSR contributions is knowledge (Iivari 2007).

Although DSR in IS has a potential to increase the practical relevance of IS research (Iivari 2007, Sein et al. 2011), the present chapter does not specifically focus on this research orientation, since it is widely discussed in the recent IS literature (e.g., Hevner et al. 2004).

Instead, this section focuses on how to make descriptive nomothetic research more design-oriented. Much of recent nomothetic IS research has been based on the TAM (Davis et al. 1989; see also Chapter 38 by Venkatesh et al. in this volume). Benbasat and Barki (2007) criticize it in that it has been weakly linked with design. Indeed, it has focused on contextual aspects such as computer anxiety, end user support, experience, gender, personal innovativeness, and self-efficacy (Lee et al. 2003) rather than on designable qualities of IT applications. Perceived ease of use, which—when operationalized as in Davis (1989)—closely corresponds to the core usability (Preece et al. 1994), is the only fairly designable quality of IT applications that has been systematically analyzed in TAM research. Other designable qualities such as system quality, information quality (≈output quality) are only occasionally included (Venkatesh and Davis 2000, Wixom and Todd 2005).*

Benbasat and Zmud (2003) recommend that IS researchers should focus on IS aspects of the phenomena instead of treating IT artifacts as a "black box." In line with their recommendation, this section suggests a set of designable qualities of IT artifacts to be considered in nomological empirical research into IT applications.

Each IT application type in Table 3.1 has essential designable qualities (see Table 3.2). Since automating applications often aim at high autonomy of the system execution, system quality—such as reliability, security, and safety—is very important in their case (e.g., embedded vehicular software systems). Augmenting IT applications, on the other hand, typically are highly interactive, underlining usability in the sense of ease of use and ease of learning. Mediating IT applications provide a medium for social

* One should note that perceived usefulness in TAM is a more dependent variable. In terms of Table 3.2, it can be expected to be dependent on functional quality, information quality, usability (≈perceived ease of use), and so on.

TABLE 3.2 Designable Qualities of IT Applications

Ideal Type	Designable Quality	Comments
Automating	System quality	System quality in the sense of DeLone and McLean (1992), excluding aspects of usability
Augmenting	Usability	Usability in the sense of ease of use and ease of learning (Preece et al. 1994)
Mediating	User-to-user interactivity	User-to-user interactivity supported by qualities such as reciprocity, multimodality, and responsiveness (McMillan 2002, Johnson et al. 2006)
	User identifiability	User identifiability covering user anonymity as a special case
Informating	Information quality	Information quality in the sense of DeLone and McLean (1992)
Entertaining	Funniness	Funniness of the characters, story, sound, graphics, interface, etc. (Davis and Carini 2005)
	User-to-system interactivity	User-to-system interactivity supported by qualities such as user control of the interaction, multimodality, and system responsiveness of the user–system the interaction (McMillan 2002, Johnson et al. 2006).
Artisticizing	Artistic quality	Artistic quality comprising technical skill and originality (Kozbelt 2004)
	Aesthetic quality	Aesthetic quality referring to the beauty of IT artifacts, covering classical aesthetics and expressive aesthetics (Lavie and Tactinsky 2004)
Accompanying	Emotional quality	The quality of emotions built in the IT artifact (Bates 1994, Fujita 2001)
Fantasizing	Identity constructability	Identity construction by choosing nicknames, wearing different embodiments (e.g., Avatars), and talking, discussing, and negotiating about various identities (Talamo and Ligorio 2001).
All	Functional quality	Does the system provide the expected or desired functionality to clients and its users or user groups?
		Does the system exclude undesired or not allowed functionality from clients, users, or user groups?

interaction between human beings. Therefore, user-to-user interactivity—such as reciprocity, multimodality, and responsiveness—is particularly significant in their case. Because information content is an essential part of IS proper, information quality is an essential characteristic of IS.

It seems obvious that computer games should be funny in some sense (Davis and Carini 2005) so that they are attractive and engaging. Just as in the case of any piece of art, "artistic quality"—that is, the technical skills and originality exhibited by the piece of art in question—is very essential in the context of computer art. In the case of digital pets, users are assumed to build a personal attachment with the pet. The pet also provides companionship (Friedman et al. 2003). Therefore, emotional quality as the quality of emotions built into a digital pet and exhibited by it is very essential in the case of this type of application.[*,†] Although one can claim that all communication includes identity construction

* Emotional quality as used in the present article is a topic of affective computing (Picard 1997), although affective computing is more interested in how computers can recognize, interpret, and process users' emotions than in producing artificial emotions in computers.

† Emotional quality differs from affective quality as defined by Zhang and Li (2005). Affective quality in Zhang and Li (2005) refers to the ability of an IT artifact to cause a change in the (core) affect of the user. Obviously, emotional quality of an IT artifact may influence its affective quality, but to my knowledge this is an unexplored territory. Sun and Zhang (2006) review the role of affect in IS research, but do not specifically address artificial emotions built in the IT artifacts.

(Hermans 2004), it is the most conspicuous in the case of virtual fantasy world applications where a user can typically choose and/or construct his/her identity on will or have a number of identities (Talamo and Ligorio 2001, Yee and Bailenson 2007). Identity constructability includes self-presentability as a special case, if the user wishes to present his/her real identity.

Table 3.2 summarizes the qualities presented earlier including a few additional ones. The final row identifies "functional quality" as a generic quality characteristic that is common to all software-based systems. ISO 9126 standard for software quality characteristics defines functionality by a question: "Are the required functions available in the software." Table 3.2 does not consider required functions or functional requirements as a reference of functional quality, but expectations and desires of clients, users, or user groups. Required functions or functional requirements as a baseline artifact in software development may more or less correspond to these expectations and desires. Functional quality also covers the question if the system excludes undesired or not allowed functionality from clients, users, or user groups. This aspect is close to compliance that is one subcharacteristic of functionality in the ISO 9126 standard (ISO 1991).

Table 3.2 identifies an application type where the relevance of the designable quality in question is most obvious and justifies its inclusion in that way. It does not, however, claim that the designable quality is relevant only in the case of that application type. As discussed earlier, IT applications in real life tend to be hybrids of several ideal types in Table 3.1. Therefore, when considering relevant designable qualities of a real application, it is justified to consider all the 12 qualities—whether or not they are relevant in the case of the IT application at hand.

Of course, one cannot claim that Table 3.2 is an exhaustive list of designable qualities of IT artifacts. For example, one could consider complementing Table 3.2 with some innovation characteristics such as complexity, compatibility, result demonstrability, and trialability (Rogers 1995). Although they can partly be influenced by design, generally they are less designable than the qualities in Table 3.2, and above all they are more general without any IT-specific substance.

The AIS website of theories used in IS research (http://istheory.byu.edu/wiki/Main_Page, accessed March 15, 2012) identifies 14 theories that have originated in IS. Of these, DeLone and McLean (1992, 2003) models and Media Synchronicity Theory (Dennis et al. 2008) are strongest in addressing designable qualities. Since the latter is very specific focusing CMC applications only, let us compare Table 3.2 with the DeLone and McLean models, which are more general. DeLone and McLean (1992) explicitly include only system quality and information quality and implicitly usability as an aspect of system quality as designable qualities. One should note, however, that the core usability differs quite a lot from more technical aspects of system quality such as reliability of the system, its maintainability (flexibility), and efficiency (resource utilization). Therefore, it is justifiable to separate it—in particular since users are the best experts to assess usability, while IT specialists are the best experts to assess the technical aspects of system quality. DeLone and McLean (2003) additionally include service quality, acknowledging that the latter may be more relevant in the case of IS functions than in the case of individual applications. Table 3.2 incorporates functional quality that resembles the "technical quality" aspect of service quality in Grönroos (1984).*

So, despite the fact that Table 3.2 is tentative, it provides a far more systematic and comprehensive list of designable qualities to be included compared with the DeLone and McLean models. As a consequence, one can imagine research inspired by Wixom and Todd (2005), for example, in which one has the qualities of Table 3.2 as independent variables and TAM/UTAUT constructs (Davis et al. 1989, Venkatesh et al. 2003) as intervening and/or dependent variables. Inclusion of all or most of the qualities of Table 3.2 as independent variables reduces the risk of specification errors. If they are

* Grönroos (1984) distinguishes two aspects in service quality: technical quality, which refers to what the customer is actually receiving from the service; and functional quality, which involves the manner in which the service is delivered. As a consequence, "technical quality" in the sense of Grönroos (1984) is close to functional quality in Table 3.2, whereas "functional quality" in the sense of Grönroos (1984) covers aspects of systems quality and usability.

systematically included, one can expect a more cumulative research tradition on designable qualities that significantly affect the success of IT applications.

3.6 Discussion and Conclusions

To summarize, the present chapter argues that IS is as a practical discipline of computing that specifically focuses on IT applications, on their development, use, and impact at individual, group, organizational, community, society, and global levels.

The major ideas of the chapter can be summarized in four points. First, the chapter encourages IS researchers to seek technological continuities and invariants in order to foster a cumulative research tradition in this world of technological change. The first question to be asked in the case of each new technology is whether or not it really is so new that it does not have any predecessors and cannot be viewed as an instance of a more general genre of technologies. If not, then one can ask how prior research into its possible predecessors and more general genre of technologies may inform the focal new technology, how the focal technology differs from existing comparable technologies, and what implications these differences may have.

To illustrate, although ERP-based IS are examples of application package-based IS, it is not a norm in the ERP literature to emphasize this continuity and to carefully review how earlier research on the implementation of application package-based IS could inform ERP implementation; "implementation" in this context covering design by the client organization (configuration and possible customization) and the final implementation. This has likely resulted in omission of relevant earlier research.*

Second, the chapter advices IS researchers to identify the extra-scientific practices (Strasser 1985) IS research aims at supporting and the associated actor groups to be informed. When suggesting practical or managerial implications of their research, IS researchers could be much more explicit in this regard. One reason is that what is actionable in practice depends on the actor groups. For example, top management support is actionable to managers but not to individual users, users' age and gender are not actionable to users and actionable to managers through recruiting at most.

Third, the chapter proposes that design of IT applications should be a central topic of IS research, because it is the key practice to be supported by IS research and because design of IT applications essentially affects the quality of IT applications and their success. Recognizing that software for most IT applications is acquired as packaged software or as prefabricated components and services, we should also pay more attention to the whole chain of design from the initial design by vendors and further design by client collectives and individual users.

Finally, the chapter suggests that IT applications can be conceptualized in terms of designable qualities. Focusing on designable qualities helps to build more IS-specific theories for explaining and predicting (Gregor 2006) than theories adopted from reference disciplines, which tend to be void of any IT-specific substance. Also many theories, which have originated in IS, tend to be fairly weak in addressing IT. For example, it is almost paradoxical that the major theoretical achievement of IS—Technology Acceptance Model (Davis et al. 1989)—is so general that it is totally empty of any IT-specific substance.† As a consequence, it can be applied in the case of almost any technology (such as farming technologies, Flett et al. 2004). One could expect that more IT-specific theories would be more informative to practitioners.

* As an example, Iivari (1986/1990) suggested a theoretical model that explains implementation challenges of application package-based information systems in terms of originality, complexity, radicalness, and divisibility of the systems. It seems obvious that these four dimensions are particularly relevant in the case of ERP-based information systems, which tend to be complex, may imply radical changes in business processes, and prefer borrowing (configuration) rather than adaptation (customization). Overall, all these three factors accentuate implementation challenges, only divisibility (i.e., modularity) of ERP systems mitigating them. Yet, the four factors and their interactions have not been systematically discussed in the ERP literature.

† The IT substance is just a matter operationalization of perceived ease of use and perceived usefulness.

Furthermore, modeling application types and specific applications in terms of variables such as designable qualities in Table 3.2 allows us to conduct more general and time-invariant research, since application types typically include several specific applications that vary in terms of designable qualities just as specific IT applications do during their evolution. For example, we have currently numerous social networking websites. When researching them, it would be advisable to include a number of sites in a study rather than a single one in order to increase "objective" variance of each designable quality. Assuming that there are standard measurement instruments for designable qualities, independent studies investigating different websites or a single website at different times are also more easily comparable.

But above all, designable qualities constitute parameters for design. Therefore, when conducting nomothetic research, this chapter suggests that the incorporation of designable qualities is primary and the inclusion of non-designable and non-actionable contextual factors only secondary. Although the latter may significantly increase the variance explained and therefore may be intellectually interesting to include, interpreting IS as a practical discipline underlines that it is more important to understand how designable qualities explain the success of IT applications and in this way to help practitioners to design better systems.

4.1 Introduction

Information technology (IT), in the narrow sense in which the term is used in particular in North America, is the newest computing discipline to emerge over the past 20 years or so. The Computing Accreditation Commission of ABET, the primary accreditation agency for programs in computing, engineering, and technology in the United States, and increasingly beyond, first promulgated separate accreditation criteria for programs in IT in 2002. The Association for Computing Machinery (ACM) and Computer Society of the Institute of Electrical and Electronic Engineers (IEEE-CS) published its first model curriculum for programs in IT in 2008 (Lunt et al., 2008) although IT was mentioned already in the 2005 overview volume (JTFCC, 2005) in which an ACM, IEEE-CS, and Association for Information Systems (AIS) joint task force compared the various computing disciplines (http://www.acm.org/education/education/curric_vols/CC2005-March06Final.pdf).

Before discussing research in IT, it is good to make a distinction between the broader use of the term "information technology" and the narrower sense in which the term will be used in this chapter. In the broader sense, the term "information technology," which was first coined by Leavitt and Whisler (1958), refers to the whole of computing and includes all the computing disciplines, including computer engineering, computer science, information systems (IS), software engineering, and the myriad of emerging computing disciplines. In this broader sense, "IT" is therefore more or less synonymous with the terms "computing" and "informatics."

In the narrower sense, the term "information technology" is defined as follows by Lunt et al. (2008, p. 9):

> IT, as an academic discipline, is concerned with issues related to advocating for users and meeting their needs within an organizational and societal context through the selection, creation, application, integration and administration of computing technologies.

With mathematics serving as the foundation, modern computer science was essentially born with the advent of the digital computer, proceeded in theory in 1931 by Kurt Gödel's incompleteness theorem and 1936 Alan Turing's and Alonzo Church's formalization of the concept of an algorithm. The first computerized business applications of the 1950s, often called electronic data processing, gave birth to the field of IS. Other scientific and engineering computing applications gave rise to software and computer engineering. By the 1990s, with the growing complexity of computing technologies, especially with the wide scale of integration provided by the Internet, IT emerged as a separate computing discipline primarily because of the workforce development needs (Lunt et al., 2008; Gowan and Reichgelt, 2010) to support the infrastructure. IT programs evolved because institutions heard from potential employers of graduates from computing programs that computer science programs often did not impart the more practice-oriented system and network administration skills in their graduates, focusing instead on the more theoretical aspects of computing. Programs in IS, on the other hand, often did not instill the required technical knowledge in their graduates, concentrating instead on issues concerning the management and use of IT in organizations.

4.2 Identity of the Field of IT

So, unlike many other new disciplines, the field of IT did not emerge out of a need to answer novel research questions, or out of a need to approach existing research questions through new methodological approaches. The discipline of IS arose out of the realization that questions regarding the use of computing technologies within organizations were not addressed sufficiently well in, for example, social and/or organizational psychology, sociology, or computer science. And one can argue that the discipline of cognitive science arose out of the realization that there was a greater need for theory building regarding and modeling of cognition than was possible in the main other discipline studying cognition, cognitive psychology. At the time of the emergence of cognitive science, psychology was still dominated by the behaviorist mind-set and attempted to explain every cognitive behavior simply in terms of the stimuli the individual received and the responses produced. Any speculation about the internal processes that mediated between stimuli and responses was frowned upon. Cognitive science was less beholden to this tradition and used the new methodology of computer modeling to approach the study of cognition.

The origin of the discipline of IT to a large extent explains the fact that it has not as yet coalesced around as clear a set of research questions as the other computing disciplines. Benbasat and Zmud (2003), refining work by Aldrich (1999) on organizational identity, argue that for a discipline to establish its own recognized identity within an existing environment, it must resolve two issues, namely, a legitimacy issue and a learning issue. The legitimacy issue itself consists of two subissues, namely, sociopolitical legitimacy and cognitive legitimacy. Sociopolitical legitimacy is conferred on a discipline when it is recognized as a separate discipline by key stakeholders, including the general public, governmental agencies, and, in the case of academic disciplines, academic administrators. IT fairly quickly obtained sociopolitical legitimacy. For example, shortly after its emergence, the Computing Accreditation Commission of ABET, the lead organization for accrediting programs in computing in the United States, and increasingly elsewhere, invited the IT community to formulate its own set of accreditation criteria. IT was also included in the efforts by the ACM, the AIS, and the IEEE-CS to formulate model curricula for the different computing disciplines.

However, the same cannot be said for cognitive legitimacy. Cognitive legitimacy is conferred on a discipline if it is recognized by others within the academic community as addressing a set of questions that are not addressed by any other discipline (such as IS did when it emerged) or when it is recognized as addressing questions that are addressed by other disciplines in novel ways (such as cognitive science). IT has not achieved cognitive legitimacy as yet. For example, there are very few PhD programs in North America in IT in the narrow sense in which the term is used here and very few research-oriented journals that focus on IT as a discipline.

However, an academic discipline is unlikely to achieve cognitive legitimacy until it can resolve the other issue highlighted by Benbasat and Zmud, namely, the learning issue. The learning issue essentially involves the community establishing a coherent set of issues to study and/or developing its own set of methodologies, theories, and concepts to approach these issues. The IT community appears to be aware of the importance of resolving the learning issue, and there are a number of papers that attempt to discuss what unique contribution the discipline of IT might make to research in computing and what an IT agenda might look like (e.g., Reichgelt, 2004; Ekstrom et al., 2006; Agresti, 2011).

Many of the papers attempting to resolve the learning issue for IT contrast the discipline with other computing disciplines, in particular the field of IS. This may reflect the fact that the field of IS, more so than the other computing disciplines, seems to periodically engage in the type of meta-level discussions that, to date, have characterized many of the research-oriented discussions in the IT community (see, e.g., Benbasat and Zmud, 2003; Myers et al., 2011). It may also reflect the fact that the field of IS is the discipline that is most closely related to IT. For example, the most recent model curriculum for IS states that IS programs sometimes go under the name "information technology" (Topi et al., 2010, p. 12).

Moreover, when trying to draw a contrast between IT and the other computing disciplines, authors tend to rely on information about undergraduate programs. For example, early in the emergence of IT as a new computing discipline, a number of studies compared undergraduate programs in computer science, IS, and IT (e.g., Hislop, 2003; Reichgelt et al., 2004; Lunt et al., 2005), both in an attempt to legitimize IT as a separate computing discipline and to show how it differed from the other computing disciplines. More recent attempts to draw a contrast between IT and the other computing disciplines (e.g., Agresti, 2011) have relied on the so-called overview volume. The overview volume was published by a combination of professional organizations in an effort to draw a contrast between the computing disciplines of computer engineering, computer science, IS, IT, and software engineering (JTFCC, 2005). One can, of course, argue as to whether the structure of undergraduate programs should be used in trying to contrast the research agendas of the discipline. In the absence of any other sources, this is as good a place to start as any.

Three themes emerge from these discussions, namely, the central role of what has been called the IT infrastructure, its deployment, and the use of integration in its creation.

4.3 Underlying Themes for the Discipline of IT

The first theme that is central to many of the discussions on how to resolve the learning issue for IT is that of the IT infrastructure. The term "IT infrastructure" is defined by van Bon et al. (2007, p. 338) as "all the hardware, software, networks, facilities etc., that are required to develop, test, deliver, monitor or support IT services." It then goes on to define an IT service as a service that is based on the use of the IT [defined as the use of technology for the storage, communication, or processing information] and supporting the customer's business processes. The IT infrastructure is a subset of the "IT artifact." The latter has figured prominently in discussions on the nature of the field of IS and is defined by Benbasat and Zmud (2003) as "the application of IT to enable and support task(s) within a structure(s) that is itself embedded within a context(s)." While there have been calls for improved conceptualizations of the IT artifact (e.g., Orlikowski and Iacono, 2001), the term, as defined by Benbasat and Zmud, encompasses not only the IT infrastructure but also the tasks, the task structure, and the task context in which the IT infrastructure is used. While there is considerable debate within the IS community as to the centrality of this concept to the discipline, with, for example, Benbasat and Zmud (2003) arguing that it had to have a central place in defining the discipline, with others disagreeing (e.g., Alter, 2003; DeSanctis, 2003; Ives et al., 2004), there is little debate within the IT community that the IT infrastructure has to

play a central role in the discipline. For example, the IT model curriculum (Lunt et al., 2008) contains the following 13 knowledge areas:

1. Programming Fundamentals [PF]
2. Information Technology Fundamentals [ITF]
3. Information Management [IM] (covering essentially database management)
4. Human Computer Interaction [HCI]
5. Social and Professional Issues [SP]
6. Platform Technologies [PT] (covering essentially hardware)
7. Networking [N]
8. System Integration and Architecture [SIA]
9. Integrative Programming and Technologies [IPT]
10. Web Systems and Technologies [WEB]
11. Mathematics and Statistics for IT [MATH]
12. Information Assurance and Security [IAS]
13. System Administration and Maintenance [SAM]

If we ignore those knowledge areas that either cover basic material or focus on general education topics (PF, ITF, SP, MATH), five of the remaining nine (IM, PT, N, IPT, WEB) directly relate to the IT infrastructure.

Clearly, the field of IT is not the only computing discipline to cover portions of these knowledge areas. For example, computer engineering covers knowledge areas such as platform technologies and networking, while software engineering and computer science would both claim to cover information management, programming (PF and IPT in the IT model curriculum), web technologies, human computer interaction, and at least some aspects of networking. IM and HCI both have a central role in the IS discipline.

However, and here is where the second theme emerges, as Agresti (2011) points out, the way in which these topics are covered in IT differs significantly from the way in which they are covered in the other computing disciplines. Agresti argues that each of the major computing disciplines has a separate theme. Thus, computer science, in its purest form, focuses on the theory underlying computing and seeks to formulate the mathematical and logical foundations of computing. Computer engineering focuses on the hardware necessary to physically realize computation, while software engineering focuses on the development of particularly the applications to run on the hardware. IS's focus is on the use of IT (used in the broader sense) to create business value and to provide support to the organization. IT, finally, focuses on the deployment of the technologies and their integration with existing systems. Agresti summarizes his analysis as follows:

Discipline	Focus
Computer Science	Theory
Computer Engineering	Hardware
Software Engineering	Development
Information Systems	Organizations
Information Technology	Deployment

The model curriculum for IT programs includes knowledge areas that are directly relevant to deployment, in particular SIA and SAM. One could also argue that the knowledge areas of IAS and HCI are related to the issue of the deployment of the IT infrastructure.

A third, closely related theme, in the IT literature is the theme of integration. There are two different ways in which this theme emerges.

The first is most directly related to the deployment theme and concerns the integration of the IT infrastructure into the organization, including users of the IT infrastructure. Clearly, this is very similar

to what the field of IS considers to be its primary domain of research, and there is a significant overlap between the two disciplines in this area. However, whereas IT tends to focus more on the individual users, as witnessed by the inclusion of HCI among the knowledge areas in its model curriculum, IS places a greater emphasis on broader organizational issues. This is not to say that IT completely ignores the organizational focus, or that IS ignores the individual user. Indeed, HCI is a thriving area of research within IS and, indeed, computer science. The difference is primarily one of emphasis. Going back to the Zmud and Benbasat definition of the IT artifact as "the application of IT to enable and support task(s) within a structure(s) that is itself embedded within a context(s)," one could argue that IT approaches the issue of HCI primarily by focusing on the application of IT to support tasks, while IS is also concerned about the organizational structures and the context in which these structures are embedded.

The second way in which the theme of integration emerges in the field of IT concerns the construction of the IT infrastructure. Whereas the fields of computer engineering and software engineering tend to focus on one element of the IT infrastructure, hardware and software, respectively, the field of IT is primarily concerned with how one can integrate existing components into a new IT infrastructure to the benefit of the organization. Ekstrom and Lunt (2003) argue that IT programs should not require students to develop a deep knowledge of how individual technology components are to be implemented. Rather, such programs should instill in their students a deep understanding of the interfaces between the component technologies. This sentiment is also reflected in the IT model curriculum, where the more advanced programming knowledge area is called "IPT."

4.4 Formulating Research Questions for IT

Having distinguished IT from the other computing disciplines, a number of questions arise when it comes to the issue of research, namely,

1. Are there a series of research questions that are unique to the field of IT and that are not covered by any other computing discipline?
2. Are there areas that are currently "claimed" by one of the other computing disciplines that could be "claimed" by IT?
3. For those research questions for which there is a significant overlap with other disciplines, is there a unique approach that IT brings and that is likely to uncover insights that are not provided by the other computing disciplines?

The questions in some way parallel the three strategies that Agresti (2011) suggests the IT community may follow in formulating a research agenda.

Agresti's first proposed strategy is to seize on "judicial vacancies," i.e., to lay claim on research questions that were never considered by other disciplines, or that are used to be but are no longer considered by another discipline. Clearly, this strategy parallels our first and third questions.

Agresti's second proposed strategy is to build a research agenda by looking at current practice and abstracting frameworks and theories from these. This particular strategy would align well with the research that is done by many IT practitioners often resulting in white papers and case studies. Whereas such material often provides valuable insights into practice, there are few attempts to extract insights from these that are widely applicable and even fewer attempts to empirically or otherwise validate the more general conclusions from these studies. Agresti's suggestion of building theoretical frameworks from practice parallels our third question. We return to this point in the next section.

Agresti's third strategy is to establish a stronger tie with a reference discipline. Agresti argues that one of the reasons for the cognitive legitimacy of some of the other computing disciplines is their strong tie to well-established reference disciplines. Thus, computer science has as its reference discipline mathematics and derives some of its cognitive legitimacy from this link. Agresti argues that IT would do well to strengthen its tie with a well-established reference discipline and suggests that it looks to systems science (Bailey, 2005) as its reference discipline.

It is of course debatable whether systems science is as appropriate a reference discipline for IT as, say, mathematics is for computer science, primarily because the discipline is not yet as widely established. However, the general notion that IT looks at insights coming out of systems science and systems engineering does seem appropriate.

4.5 Research Questions Emanating from the Underlying Themes for IT

Given the absence of a well-established research tradition in IT, many of the answers to the three questions posed on the previous section are likely not to be unanimously agreed to by the IT community. In many ways, this chapter is, therefore, more intended as a catalyst for further discussion on IT research both within the IT community and within the larger computing research community. However, given the themes of the central role of the IT infrastructure, its deployment, and the use of integration in its creation, we can start formulating some tentative answers.

The use of integration in the creation of the IT infrastructure in particular is likely to lead to a series of research questions that are unique to IT. The following examples, in particular, are relevant:

First, is it possible to develop a framework to predict some of the emergent properties of the IT infrastructure, based on the value of that property in the components that were integrated and the way in which they were integrated to create the IT infrastructure? For example, given some value of the level of security provided by each of the components integrated into a particular IT infrastructure and the methods used to integrate them, is it possible to make some predictions about the level of security provided by the resulting system? One can ask similar questions, of course, about availability, cost of ownership, and so on. Moreover, those questions can also be asked about more dynamic system performance-related issues, such as throughput and power consumption.

The framework question also allows one to draw a cleaner distinction between the questions one might pursue as an IT researcher and related questions one might ask as a researcher in a different computing discipline. For example, computer scientists and computer engineers, in particular network engineers, are likely to be able to provide measures of security, availability, etc., as far as individual components are concerned. Thus, a computer scientist or software engineer will be able to answer questions about how vulnerable a particular software application is to malicious attacks, while a computer engineer may be able to answer questions about how easy it is to hack into network traffic on a particular type of network. Similarly, an IS researcher is very likely to be able to answer questions about the integration of the IT infrastructure into the organization and what factors need to be taken into account to ensure that security risks are minimized. However, the emphasis on the IT infrastructure itself is unique to IT.

Clearly, once developed, the framework should also have the ability to predict how the integration of a new component into an existing IT infrastructure is likely to affect the properties of the overall infrastructure. How will security be affected by the integration of some cloud-based service into the IT infrastructure? What effect will it have on availability, access, reliability, etc. Again, what sets IT apart in this respect from, in particular, IS is the emphasis on the IT infrastructure. The field of IS has interesting insights to offer on how the introduction of a new aspect may affect organizational performance, but its focus is exclusively on the organization and on the individuals within it. It does not concern itself with the IT infrastructure as an entity in its own right.

A second related question concerns issues to do with trade-offs between different aspects of the IT infrastructure. For example, it is possible to provide top-quality user support by making available a personal assistant to every user of the IT infrastructure, but clearly this is not feasible from a financial point of view. Similarly, it is possible to fully secure the IT infrastructure by denying access to any user, but this also is impractical. The question that follows from this is whether it is possible to arrive at a high-level framework for determining the optimum point on various trade-offs. For example, what is

the most appropriate point on the security–availability trade-off, what factors determine the appropriate point on this trade-off, and how are these factors weighted in a given organization?

Again, the question about trade-offs is not unique to IT. For example, the space–time trade-off is a well-known principle in computer science and computer engineering. Similarly, concerns about the cost/benefits trade-offs of IT applications underlie IT business value analysis, a subfield of IS. The main question of IT business value analysis is how IT impacts organizational performance of firms both at the intermediate process level and at the organizational level, and both in terms of (internal) efficiency and (external) in terms of competitiveness (Melville et al., 2004).

Similar concerns about trade-offs between costs and otherwise desirable properties of software applications, such as maintainability and loose coupling, also underlie Boehm and Sullivan's proposal that software engineering research pay greater attention to software economics (Boehm and Sullivan, 2000). Software economics proposes to bring economic reasoning about product, process, program, portfolio, and policy issues to software design and engineering. There is an obvious similarity here with IT in that one part of the IT research agenda is aimed at bringing reasoning about processor, process, program, portfolio and policy issues to the creation, implementation, and management of the IT infrastructure.

However, IT again brings a unique perspective on questions related to trade-offs and significantly broadens these concerns. The trade-offs considered in IT concern all aspects of the IT infrastructure and, as a result, concern a larger number of trade-offs than those considered in other disciplines. Thus, computer science and computer engineering restrict themselves to the space–time trade-off, whereas IT business value and software economics tend to concentrate on the trade-off between certain aspects of the IT infrastructure and value, where value is typically defined in financial terms. While the financial and organizational aspects are relevant to IT as well, IT also considers more technical trade-offs between different properties of the IT infrastructure, including cost and value, security, availability, usability, and scalability.

There are also a series of research questions that follow from the theme of deployment of the IT infrastructure. Whereas other computing disciplines have contributions to make to questions related to the creation of components of the IT infrastructure and/or to questions related to the deployment within an organizational framework, IT uniquely considers deployment from a technical point of view.

The theme of deployment is most closely aligned with Agresti's suggestion that IT attempts to build theoretical insights from practice. As we stated earlier, there is a lot of anecdotal evidence on the value of certain processes, procedures, and best practices in deploying (aspects) of an IT infrastructure, often in the form of case studies and white papers, and often published by IT practitioners. While this material is extremely valuable, the research reported in it often does not meet the standards of rigor that is expected in academic research. In addition, almost no attempt is made to generalize from these case studies. As a result, such studies are often rejected by academic researchers.

However, the fact that the research as it stands does not meet the standards set by the academic community does not mean that it should be dismissed out of hand. As an academic discipline, IT might try to take some of this anecdotal information and turn it into scientifically validated theories. For example, there are a large number of studies available from IT consulting firms demonstrating the usefulness of adopting best practices as documented in the IT Infrastructure Library (ITIL) to improve the quality of the IT service delivery. Such papers provide valuable insight into practice and a thorough analysis of such papers might lead to the type of insights regarding the IT infrastructure that are unlikely to be obtained by following the more traditional scientific methodologies adopted by the other computing disciplines, in particular IS, which involve formulating a hypothesis based on a more widely adopted theory and testing that hypothesis. One can, of course, create similar research projects also around other IT best practice frameworks, such as CoBIT.

A related deployment-related series of questions concerns the derivation of theoretical insights, including best practices, from anecdotal information about other deployment-related issues, including business continuity and virtualization and cloud computing. In all cases, the thrust would be from documented case studies to general insights.

The theme of deployment and integration of the IT infrastructure within a structure of tasks to be performed by an end user also provides another avenue for IT research. While the various issues identified earlier do not appear to have been researched in a more abstract way, there is a growing literature on the use of the IT infrastructure within a particular application domain. A good example is provided by the health care industry where there is a growing number of well-established and well-regarded scientific journals on the use of IT to support health care delivery, including, for example, the *BMC Medical Informatics and Decision Making*, *Journal of the American Medical Informatics Association*, and the *Journal of Biomedical Engineering and Computing*. Moreover, one often finds articles related to the deployment of the IT infrastructure in journals that appear to be more geared to health care providers. For example, there are a number of articles on the inappropriateness of the interfaces to many electronic health records in such journals as *Critical Care Medicine* (Ahmed et al., 2011), the *Journal of Oncology Practice* (Corrao et al., 2010), and *Current Oncology Reports* (Markman, 2011). Health care delivery is but one example. One can find similar examples for many other domains, including education, criminal justice, and the military.

However, just as there typically is no attempt to generalize from the case studies published by IT practitioners, there typically is no attempt to generalize the lessons learned about the IT infrastructure, its deployment, and the use of integration from one domain to another domain. For example, are the issues of information assurance and security and the consequences that it has for the design of the IT infrastructure that arise in the health sector significantly different from the way these issues arise in the field of education? If so, why; what specific features of these application domains lead to these differences? Again, the thrust would be from domain-specific insights to more general insights and theories.

4.6 Conclusion

The discipline of IT, uniquely among the computing disciplines, primarily emerged in reaction to workforce development needs, rather than as reaction to a need for finding answers to new research questions, or to a need to employ new research methodologies to existing questions. As a result, it has not yet developed the strong research tradition that the other computing disciplines have developed. Thus, there are very few PhD programs in IT, and there are no recognized avenues for publishing high-quality IT research.

However, the IT community is acutely aware of this need to address this issue. It knows that in order to obtain legitimacy in the academic community, it must solve the learning issue for the discipline and arrive at a set of the research questions and/or research methodologies that it can legitimately claim as its own. One can expect IT research to emerge organically, especially as the consensus within the community about what sets IT apart from the other computing disciplines. However, such organic growth will take time and will, in any case, be encouraged through a meta-level research discussion about what an IT research agenda might look like.

This chapter has argued that the unique nature of IT as focusing on the IT infrastructure, the use of integration in its creation, and its deployment raises a series of questions to which IT can bring a unique focus. It has also argued that a practice-driven formulation of theories provides a unique methodological approach. The hope is that the points made in this chapter will help fertilize and expedite the organic growth of IT research that the IT community is so keenly looking forward to.

Sociotechnical Approaches to the Study of Information Systems

Syracuse University

5.1 Sociotechnical Premise

Through this chapter, we introduce and explain the sociotechnical premise relative to the study of information systems (IS). The sociotechnical premise can be articulated as (1) the mutual constitution of people and technologies (and, specifically, digital technologies*), (2) the contextual embeddedness of this mutuality, and (3) the importance of collective action. Some readers will value this chapter for its breadth of coverage. Established sociotechnical scholars will likely thirst for more advanced discussions than what we provide here. Some readers will value the material in this chapter for identifying particular debates, current themes, or emerging approaches. We see this as a special opportunity and focus on these topics at the chapter's end.

* For this chapter, we use technology to mean digital technologies, information and communication technologies (ICT), information technologies, and computer technologies. So, technology here is more narrowly circumscribed (than all kinds of technologies) but inclusive (of digital technologies) conceptual shorthand.

We begin by noting the widespread ethos within the IS research community that it is sociotechnical by definition. As Allen Lee notes:

> Research in the information systems field examines more than just the technological system, or just the social system, or even the two side by side; in addition, it investigates the phenomena that emerge when the two interact. This embodies both a research perspective and a subject matter that differentiate the academic field of information systems from other disciplines. In this regard, our fields so called reference disciplines are actually poor models for our own field. They focus on the behavioral or the technological, but not on the emergent sociotechnical phenomena that set our field apart. For this reason, I no longer refer to them as reference disciplines, but as contributing disciplines at best (Lee 2001, p. iii).

Our goal in writing this chapter is to encourage scholars to move beyond this rhetorically pleasant articulation of sociotechnical thinking toward more deliberate conceptual development, increased empirical activity, and greater methodological capacity.

5.1.1 Mutual Constitution

Sociotechnical research is premised on the interdependent and inextricably linked relationships among the features of any technological object or system and the social norms, rules of use, and participation by a broad range of human stakeholders. This mutual constitution of social and technological is the basis of the term sociotechnical. Mutual constitution directs scholars to consider a phenomenon without making *a priori* judgments regarding the relative importance or significance of social or technological aspects (e.g., Bijker 1987, 1995; Latour 1999).

Mutual constitution differs from social determinism as social determinists see information and communication technologies (ICTs) as being caused by or created for the organizational needs and peoples' decisions about how to meet those needs (albeit, imperfectly at times). In particular, socially deterministic researchers contend there cannot be any specific "effects of technology" attributable to the material qualities of technology. That is, the "cause" and the nature of "particular effects" are always social interpretations (Grint and Woolgar 1997).

Mutual constitution stands apart from technological determinism, which regards the technology as the main cause of organizational change. Technological determinists characterize ICT as an independent (and often the primary) variable. The essence of this cause-and-effect relationship is conveyed by the word "impact." Technology is seen as an exogenous, independent, and material force that determines certain behavior of individual and organizations, producing predictable changes in organizational traits such as structure, size, decision-making, work routines, and performance (e.g., Leavitt and Whisler 1958; Pfeffer and Leblebici 1977).

Mutual constitution implies (1) both humans and technologies may have some sort of agency (some ability to act) in a given situation and (2) these actions are not deterministic (actions are not independent of surrounding events). The underlying premise of mutual constitution is coevolution among that which is technological and that which is social. The focus on interdependency among technology and human organization is done by attending to material triggers, actions of social groups, pressures from contextual influences, and the complex processes of development, adoption, adaptation, and use of new (digital) technologies in people's social worlds (Jones and Orlikowski 2007). Directionality is a property of the situation, not inherent to a relation.

Why is this important? Barley (1988) argues a singular focus on the material aspects of technology leads researchers into inappropriate materialism. On the other hand, a focus on technology as a solely social production has led to an overreliance on social orders as primary drivers, potentially leading to social determinism. In contrast, the sociotechnical perspective, and in particular the principle of mutual constitution, speaks directly to the complex and dynamic interactions among technological capacities, social histories, situated context, human choices, and actions rather than looking for simplified causal agency.

5.1.2 View of Context

The second element of the sociotechnical premise is that all technologies are socially situated. Any IS or ICT is embedded into a social context that both adapts to, and helps to reshape, social worlds through the course of their design, development, deployment, and uses (e.g., Kling 1980; Land and Hirschheim 1983; Orlikowski 1992; Walsham 1993; Avgerou 2001). This situated and mutually adaptive conceptualization stands in contrast to much of the current IS research that is "… de-problematized <of> time, space and the uses of ICT" (Lee and Sawyer 2009, p. 3), which is self-limiting in its failure to recognize the depth of social engagement. The desire for such an a-contextual perspective on IS (and ICT) continues to fascinate scholars (e.g., Brynjolfsson and Hitt 1996). However, this discourse, through its own framing, fails to account for social changes within which technological innovations unfold (e.g., Fleck 1994).

Adherents to de-contextualized models of IS pay too little attention to the environment of the organization and temporal dimension of technological innovation. For example, the literature focused on investigating the strategic implications of IS has sought to provide guidance for how to best harness strategic potential of new ICT/IS as a source of competitive advantage (e.g, Earl 1989; Morton 1991; Hammer and Champy 1993; Porter and Millar 1985). However, the depiction of an organization's environment does not typically delve into the complicated social processes that embed technological innovation within organizational or social contexts. In addition, these appraoches tend to ignore the temporal dimension of ICT. More than 20 years ago, Orlikowski and Baroudi (1991) found nearly 90% of IS research represents a single-snapshot data collection method, which does not include observations and data collection over time. This continues today (e.g., Avital 2000; Pollock and Williams 2009).

In contrast to a-contextualized and detemporalized approaches, the sociotechnical perspective is premised on the embedding of the ICT/IS into the more complex world of situated action: a world that is tightly tied to the characteristics of where the actions occur. In their analysis, sociotechnical scholars focus on situating work and seek to examine all contextual factors. This type of inquiry leads to a holistic view of context: one that does not diminish or remove contextual elements, even those with limited influence. In this situated view, context is not taken as fixed or delineable but is defined dynamically. Sociotechnical approaches focus on building situational and temporal conditions directly into their theories, relating these to conceptualizations of ICT/IS (e.g., Dourish 2004).

5.1.3 Collective Action

The third element of the sociotechnical premise is collective action: the pursuit of goal(s) by two or more interested parties (Merton 1968). Collective action undergirds the concept of organization (and all sociality) without implying positive or negative outcomes: there are shared pursuits. So (and typically), multiple parties pursue different goals, creating conflict. The underlying premise is the joint pursuit of one or more shared goals by two or more parties, focusing on the design, development, deployment, and uses of a particular ICT or IS, is both shaped by, and shapes, the nature of collective action.

Collective action means that joint interests and multiple goals are intertwined with both the context and the technological elements. Contemporary sociotechnical research focuses less on individual workers and simplified social situations—such as worker/manager differences—to attend more complex problematizations of social settings and tensions of multiple parties such as distributed online organizing (Sawyer and Eschenfelder 2002; Kling 2007).

5.1.4 Sociotechnical Premise in Contemporary IS Research

Sociotechnical approaches differ from what Kling and Lamb (2000) call "the standard model" of an IS. Standard models of IS focus on the technological aspects and pay far less attention to social roles and

structures.* Second, standard models of IS decontextualize the work in search of generalities and best practices. Third, standard models of IS emphasize the cognitive and behavioral aspects of people's involvement with technologies.

The sociotechnical approach eschews simplifying rationales that seek a single or dominant cause of change. Instead, sociotechnical approaches foreground both the complexity and the uncertainty involved in the process of technologically involved change. In contrast to socially or technologically deterministic views, sociotechnical approaches require a detailed understanding of dynamic organizational processes and the occurrence of events over time in addition to knowledge about the intention of actors (situated rationality) and the features of technologies. As a result, studies in this stream of work construct neither independent nor dependent variables but instead adopt process logic to investigate the reciprocity and coevolution of the contextual interactions and outcomes (Barrett et al. 2006).

Sociotechnical researchers focus attention to the heterogeneous networks of institutions, people, and technological artifacts that together play roles in the design, development, deployment, take-up, and uses of any particular IS (Kling et al. 2003). So, as Michel Callon and John Law put it, any distinction between ICT (or IS) and society as context is an oversimplification that obscures the complex processes where human and technologies jointly construct sociotechnical entities (Callon and Law 1989).

5.2 Historical Roots and Conceptual Developments

In this section, we outline the historical roots of sociotechnical research.

5.2.1 Tavistock Tradition

The term "sociotechnical" was coined by researchers at the Tavistock Institute of Human Relations in England (Mumford 2000). The Tavistock Institute was founded in London in 1946 under the auspices of the Rockefeller Foundation. Its initial mission was to weave together social and psychological sciences in order to benefit a society damaged by the effects of the Second World War. Tavistock researchers, including therapists and a wide variety of consultants, strove to formulate techniques that could help to rehabilitate war-damaged soldiers (Jones 2004). Some Tavistock scholars came to believe that the same techniques could be employed in support of a more humane (and human-centered) organization of work in industry. These scholars suspected the Tavistock techniques would be applicable to the work of lower-rank employees who spent most of their time on routine and simple tasks without any clear prospect for job satisfaction or personal development (Mumford 2000).

This extension of the Tavistock agenda to the workplace showcased two attributes of sociotechnical scholarship that unfolded in quite different ways over time. The first, and most prominent, attribute is the close association between the technological and the social (sub-) systems of organizations. The technological elements, perceived as machines and associated work practices by Tavistock's researchers, were not meant to be the sole controlling factor when a new technological system was implemented. Tavistock scholars advocated equal attention should be paid to providing a satisfactory work environment for employees. In this regard, the main innovation of the Tavistock research was the design of technology-supported work arrangements that could enrich work practices using multiskilled jobs with workers organized into teams. The sociotechnical approach was, in this way,

* There exists an insightful body of IS literature focusing on social analyses of IS and ICT (Avgerou et al. 2004). These social analyses of IS and ICT emphasize the social and behavioral activities which frame and underpin the development, deployment, and uses of any ICT or IS. Social analysts take a strong social constructivist view on the sociotechnical relationships. Many social analyses draw on sociotechnical theories. But they take a "weak constructionist" view of the ICT. That is, the technological elements are seen primarily as an outcome of social practices and social forces, with the technology having little or no agency or impact. Our articulation of the sociotechnical premise differs primarily in the elevation of the importance of the ICT's and IS's roles—we assign some agency or the potential for direct effects to be of the ICT's doing. In all other ways the sociotechnical perspective is very similar to the social analytic perspective.

a rebellion against the evolution of work-design practices of the time (that took an instrumental view of work and the workforce).

The second attribute of the Tavistock approach was the importance of worker involvement. At its core, Tavistock's sociotechnical approach was interventionist and activist. As we note later, this orientation to worker's interests and activism underlies the action-research orientation of Enid Mumford's Effective Technical and Human Implementation of Computer-based Systems (ETHICS) and Peter Checkland's Soft Systems Method (SSM) (Mumford and Weir 1979; Checkland 1995), the participatory design principles that characterize the Scandinavian and Nordic scholarship, and perhaps some of the more contemporary design-centric approaches to IS.

The Tavistock researcher's fundamental goal was to humanize jobs through redesigning work practices and workplace technologies while propagating democracy at work. This led to the formulation of theories that entailed concepts like "quality of working life" (Kling and Lamb 2000). These theories postulated that employees who were involved in the work system should be given a voice in the design process to determine how the new system could improve the quality of their work. In addition, the practical side of the sociotechnical approach sought to give equal weight to both technical and social aspects in the design process.

5.2.1.1 Early Developments of Sociotechnical Approaches in IS

The Tavistock approach to sociotechnical design inspired a number of researchers in the nascent field of IS. Enid Mumford, greatly influenced by her association with the Tavistock Institute, is considered to be the most influential researcher to initiate sociotechnical research within IS (Davenport 2008). She, along with her peers such as Frank Land and students (Land 2000), voiced concerns that the bulk of IS research and professional know-how were limited to engineering approaches that centered on the effective construction of reliable technical artifacts.

Mumford's work placed the social context and human activities/needs at the center of IS design. The essence of the early sociotechnical discourse in IS is found in the proceedings of the "Human Choice and Computers" conference (Sackman 1975). The overall tone was critical of the perceived computer's impact on social institutions like the social order of in the workplace.

Findings from projects across the 1960s and 1970s were consolidated by Mumford and her colleagues and students and gave rise to an information systems development methodology called ETHICS (Mumford and Weir 1979). This methodology drew upon sociotechnical principles and involved a double-design effort: the design of IT-based systems/IS and the design of work processes. Initially, the two design efforts were conducted separately. The design of IS followed the technical system analysis method, whereas the design of work processes was aimed at the elicitation of "job satisfaction" requirements of workers. The latter analysis involved the application of work quality principles such as multi-skilled jobs. The two streams of design were brought together to achieve a "sociotechnical optimization" (Mumford 2006).

In ETHICS, the starting point was work design, rather than system design, and the methodology placed emphasis on the interaction of technologies and people.* The main objective of the method was to develop IS that are both technically viable and entail social qualities that would lead to high worker satisfactions (Mumford and Weir 1979). To this end, an IS designed to solely meet technical requirements is "likely to have unpredictable human consequences" (Mumford and Weir 1979, p. 13). Therefore, ETHICS uncompromisingly elevated socially-centered approaches to system design and called attention to scoring the quality of working life in terms of fit between personal achievement and organizational goals.†

* More recently, Alter's work systems (Alter 2006) approach has rekindled interest in this approach, though his conceptual frame is not rooted in Tavistock or sociotechnical thinking.

† At about the same time, Peter Checkland advanced SSM as an IS design approach. Similar to ETHICS in its attention to human and technological subsystems, the conceptual framing builds from systems theory (see Checkland 1998, 1995).

5.2.1.2 Industrial Engineering/Human Factors

Scholars from other intellectual communities also drew from the Tavistock work, translating the sociotechnical principles into new intellectual communities and, in turn, impacting practice. One of the most successful of these translators was Albert Cherns (1976, 1987). Cherns was an associate of the Tavistock Institute and published his summation of sociotechnical design principles in *Human Relations* (see Table 5.1). The design principles Cherns laid out quickly gained prominence in the intellectual communities concerned with ergonomics, human factors, and large-scale systems design and usability.

For IS, Cherns' sociotechnical principles were translated and introduced through two articles by Bostrom and Heinen (1977a,b).* This translation emphasized the computer-based IS as the focal technological subsystem and centered attention on its design rather than on the Tavistock principles of quality of working life. Bostrom and Heinen further problematized, and constrained, the social subsystem in two ways. First, they characterized the social aspects of an IS as emphasizing the tension between worker's interests and manager's interests. Second, Bostrom and Heinen defined workers (but not managers!) as users.

TABLE 5.1 Chern's Principles of Sociotechnical Systems

Compatibility	The design process should be compatible with its objectives. If the design is intended to foster democracy in work situations, the design processes themselves must be democratic.
Minimal critical specification	No more should be specified than is absolutely essential. However, the designers should ascertain what is essential.
The sociotechnical criterion	Variances, as deviations from expected standards, must be kept as close to their point of origin as possible. In other words, solution to problems should be devised by the groups that directly experience them, not by supervisory groups.
Multifunctionality principle	In order for groups to respond to the changing work environment, they need a variety of skills. These include skills that go beyond what day-to-day production activities require.
Boundary location	Boundaries exist where work activities pass from one group to another and where a new set of skills is required. However, boundaries should facilitate knowledge sharing. All groups should be able to learn from one another despite the existence of the boundaries.
Information	Information must reside where it is principally needed for action. A sociotechnical design gives the control authority to the groups whose efficiency is being monitored.
Support congruence	A social support system must be in place to enjoin the desired social behaviors.
Design and human values	High-quality work involves 1. Jobs to be reasonably demanding 2. Opportunity to learn 3. An area of decision-making 4. Social support 5. The opportunity to relate work to social life 6. A job that leads to a desirable future
Incompletion	Practitioners must recognize the fact that the design is an iterative process. It never stops. The new changes in environment require continual revisions of objectives and structures.

* See also the more recent work of Clegg (2000).

Bostrom and Heinen's problematization of the social system as workers versus managers, and their definition of workers as users, likely reflects contemporary management thinking of the 1970s in the United States. Contemporary scholars, such as Avgerou et al. (2004), who have built from and extended the Tavistock approaches to sociotechnical scholarship, are consistently critical of the conceptual limitations of this managerialist reframing and the diminished emphasis on humane design. And, while the Bostrom and Heinen papers are cited, their work has had a lesser impact on methods and concepts in IS than might be expected given the rhetorical enthusiasm for sociotechnical claims of IS.

5.2.1.3 Participatory Design and Worker Involvement

The importance of worker participation, fundamental to the Tavistock approach, was widely adopted in practice (Land et al. 1979; Land and Hirschheim 1983). In its original sense, user participation encouraged all intended users to be involved in all IS development tasks and stages. However, across the latter part of the twentieth century, user involvement was implemented in a much more limited way: Users were typically consulted primarily to learn about the tasks and the technical systems that support them, then not involved in the rest of the design process (Land et al. 1979).

However, the sociotechnical ideals of the Tavistock Institute found fertile ground in Scandinavian countries. In the late 1960s, "the Norwegian Industrial Democracy Projects" introduced the principle that technology innovation should improve work practices along with productivity measures (Thorsrud 1970). This was meant to empower employees to organize their own jobs. In the 1970s, figures like Kristen Nygaard—and more recently Bo Dahlbom, Pelle Ehn, Erik Stolterman, and their students—pioneered the Scandinavian approaches to the social analyses of computing. This approach reflects a strong orientation toward worker involvement in designing IS and attends to both the quality of working life and the potentially humanizing power of ICTs.

Perhaps the Tavistock approach garnered attention in Scandinavia because it resonated with the sociopolitical context grounded in deep appreciation for workers' right (Sawyer and Tapia 2007). This tendency was also reflected in the principles of participatory design (PD) and more recently activity theory-centric approaches (Kuutti 1996).* In addition, the information system development methodology suggested by Mumford in the United Kingdom has been tried in Denmark and Sweden (Bjorn-Andersen and Eason 1980; Hedberg 1980). To this day, PD and social-theoretically inspired analyses of computing underpin much of information system research in the Scandinavian and Nordic countries (Iivari and Lyytinen 1998).

Despite its promising principles, sociotechnical design in IS failed to proliferate outside of the United Kingdom, Scandinavia, and the Nordic countries. During the 1990s, economic, business, and technological arenas witnessed dramatic changes; the consequences turned out to be frustrating for advocates of sociotechnical design. In the harsh competitive environment, corporations were forced to embark on methods like lean production and business process reengineering that took little consideration of employees' needs or their quality of working life (Kling and Lamb 2000). As Carr (2008) notes, pointedly, the focus in corporate IT over the past 15 years has been to routinize, automate, and outsource. And, despite its progress in places like Scandinavia and the Nordic countries, few contemporary organizations were interested in adopting PD and sociotechnical design approaches.

Workplace trends across the 1990s had companies creating flatter hierarchies and encouraged people to see innovative companies as requiring highly skilled groups to work together as members of high-performance teams. While these trends expanded these organizational member's responsibility and autonomy, this also created a more divided workplace as only high-status groups gained these benefits.

* An entire intellectual community, centered on participatory design, has grown up and meets every other year (see http://pdc2012.org/about.html) to advance sociotechnical design principles. Many of the leading scholars are known to the IS community but are more likely to publish in computer–human interaction (CHI) or computer-supported cooperative work (CSCW) venues.

Lower-status positions (e.g., service, support, and administrative) were often outsourced or transferred to temporary employment and given far less voice or status in the contemporary firm. This segmentation of the workforce further undermined sociotechnical approach, which targeted broad groups of organizational members (Mumford 2006).

5.2.2 Sociological Perspective on Sociotechnical Systems

Independent (at first) of the Tavistock efforts, in the late 1960s, some scholars in sociology began a stream of theorizing on the roles of ICT (e.g., Joerges 1990). These scholars typically focused on ICT relative to social structures such as groups, communities, organizations, social stratifications/societies, and changes in power and equity (e.g., Latham and Sassen 2005). The focal interest of sociologists, however, has led them to foregrounding macro-sociological interests relative to the roles of ICT in and of society. So, computing continues to be a tertiary topic for contemporary sociologists.*

The sociological perspective on sociotechnical systems unfolds in discourses that Kling (1980) sought to capture and articulate as belonging to the rhetoric of either "systems rationalists" or "segmented institutionalists". Systems rationalists focused on the positive, intended, and often technologically inspired opportunities from computing and automation of the workplace. Segmented institutionalists focused on the importance of social power, conflict, and pursuit of noncommensurate goals as the undergirding of any computerization activity.

And, as we turn to later, Kling and his colleagues thundered against the naïve simplifications of systems rationalists. In doing so, Kling and colleagues advanced—through empirical, methodological, and analytical efforts—a range of segmented institutionalist approaches to the sociological analysis of computing (Wellman and Hiltz 2004). This approach was not pursued by many computer scientists or IS scholars and even fewer sociologists (as Kling [2003] himself rued in a posthumously published reflection on his work). Many sociologists continue to grapple with the roles of ICT in social life, albeit with little attention to the work of Tavistock scholars, the IS community in Scandinavia, the Nordic countries, the United Kingdom, or the Kling-inspired colleagues in North America.

In the 1990s, new research interests in the social dimensions of IS emerged. These were directed to the relationships among IS development, uses, and resultant social and organizational changes. The new stream of research has offered fresh insights into the emerging role of ICT within differing organizational contexts (e.g., Kling and Scacchi 1982; Orlikowski 1992; Walsham 1993; Hirschheim et al. 1996). Drawing directly on sociological theories of institutions, this wave of sociotechnical research has informed, if not directly shaped, IS scholarship (Avgerou 2002). The sociological theories leveraged by the new stream of sociotechnical research had flourished in parallel with the early sociotechnical approaches, while they similarly dispensed with technological determinism. Even though not explicitly using the term "sociotechnical," these sociological theories offered a solid basis upon which emerging sociotechnical research built. In the following section, we discuss institutional theories, structuration theory, social network perspective, and social philosophy that proved to be instrumental in the creation of this scholarly space.

5.2.2.1 Institutional Theories

Institutional theories in organization studies emerged as a counterpoint to organizational theories that saw people as rational actors. In contrast, institutional theories focused on cultural and normative explanations for organizational phenomena (DiMaggio and Powell 1991). Barley and Tolbert (1997, p. 93) note: "… organizations, and the individuals who populate them, are suspended in a web of values, norms, rules, beliefs, and taken-for-granted assumptions, that are at least partially of their own making."

* With this noted, there is a thriving community of sociologists interested in online communities and the nature of social networks (see Wellman et al. 2001 among others).

The institutional perspective is premised on the concept of "institution" that denotes the importance of authoritative, established, and rule-like procedures that provide order in society.

A key aspect of institutions is their interest in continuing to exist. As institutions become taken for granted, people are likely to believe that there is a functional rationale for their existence, and therefore, their validity is not questioned by social actors. By employing the concept of "institution," new intuitional theorists build a conceptual basis for delineating contextual influences and the broader influences of organizations' social environments.

From an institutional perspective, ICT is viewed not as a set of material features functioning according to the functional rules that are inscribed into their physical components but as a product of embeddedness into social institutions (Avgerou 2002). In this way, ICT can be considered as an institution in its own right, one that interacts with other institutions in modern society. As an institution, ICT can be characterized as emergent, embedded, evolving, fragmented, and connected to an ephemeral social presence that is shaped as much by other institutional and contextual forces as by technical and economic rationales (Orlikowski and Barley 2001). Examining the interactions of ICT with other intuitions, Swanson and Ramiller (1997) conclude that institutional forces are significant in shaping the perception about the organizational potentials of ICT. Avgerou (2000), building from the institutional perspective, captures the process of IT-enabled organizational change with both the ICT innovation and the organizational practices considered to be institutions, each having its own mechanisms and legitimating elements. In this way, the interaction between these two types of institutions is theorized as the dual processes of institutionalization of IT and deinstitutionalization of established organizational structures and practices.

While institutional theory provides a powerful framework for understanding the context of organizational change, its pillars rest upon the assumptions of stability, persistence, and the limited scope for change. By overstressing stability and the robustness of institutions, this often underestimates the role of human agency and ignores their potentials in transforming institutional patterns (Barley and Tolbert 1997; Dacin et al. 2002). By the same token, ICT artifacts also retreat to a secondary position in institutional analyses. In fact, the institutional perspective does not inquire into the nature of the technological artifact and does not address whether IT itself can represent any material influences independent of institutional forces.

5.2.2.2 Structuration

Many scholars have theorized about the mutual constitutions of individuals and society (e.g., Bourdieu 1977; Urry 1982; Bhaskar 1998); however, it was the work of Anthony Giddens that introduced the concept of structuration to a wide range of social sciences (Bryant et al. 2001, p. 43). Through the concept of structuration, Giddens (1986) rejects the traditional characterizations of social phenomena as determined by either objective social structures or totally autonomous human agents. In his view, social phenomena are neither structure nor agency but are continuously constituted in their duality. Giddens adopts an unconventional definition of structure as "rules and resources, organized as properties of social systems" that exists only as structural properties (Giddens 1989, p. 258). Human agents draw on social structures in their actions, and at the same time, these actions produce or reproduce social structures. In this sense, action and structures are in a recursive relationship, and this is the meaning imparted by the term "structuration."

Structuration's dynamic conception of structure, as being recurrently produced and reproduced through situated interactions of people, facilitates studying technological change (Orlikowski 2000). The fundamental duality of actions and structures as featured in the theory helped IS researchers to break away from both technological and social determinism (Markus and Robey 1988). Early champions of structuration theory in IS research employed the theory to link the context and process of change, examining the ways ICT contributes to the structuring of organizations (Orlikowski and Robey 1991; Walsham and Han 1991; Orlikowski 1992). DeSanctis and Poole (1994) developed an IS-specific version of the theory called Adaptive Structuration Theory (AST). AST focuses on (1) structures that

are embedded in the technologies and (2) structures that emerge as human actors interact with those technologies. Scholars have noted the inconsistency of AST as: Giddens theorized that structure cannot be inscribed or embedded in technology since they do not exist separately from the practices of social actors (Jones 1999).

Rejecting the hypothesis of structure as embedded in technology, subsequent interpretations of structuration theory in IS gave more weight to agency, focusing attention on improvisation, enactment, and the emergent nature of ICT-enabled organizational practices (Orlikowski 1996; Orlikowski and Hoffman 1997; Weick 1998). The shift from technology as an embedded structure toward agency of humans underpins the practice lens (Orlikowski 2000; Schultze and Orlikowski 2004). She proposes the notion of technology-in-practice, which refers to the structure of technology use enacted by social actors while they interact recurrently with a particular technology artifact. Seen this way, technology-in-practice is emergent and enacted, not embodied or appropriated.

Despite its potential for explaining the social processes through which ICT and organizations interconnect, structuration theory has limitations for empirical IS research. For instance, Giddens makes almost no references to IS or ICT in his writings (Jones and Karsten 2008). In structurational analyses, technologies can have a material influence on human actions, but the effects are contingent upon how social actors engage with them through their practices. Thus, "… as they do things in relation to machines and so forth, these are the stuff out of which structural properties are constructed" (Giddens and Pierson 1998, p. 83). What this "relation to machines" might be, and how it affects social actors' practices, however, is not elaborated in structuration theory, and analysis of these properties remains largely underdeveloped (Jones and Orlikowski 2007). Moreover, structuration theory deals with social phenomena at a high level of abstraction. This leads to it being seen as a "metatheory": a way of thinking about the world, rather than an empirically testable explanation of organizational practices.

5.2.2.3 Social Network/Structure

The social network perspective first blossomed in the 1920s at Harvard University's Department of Sociology. Since then this approach has been taken up and advanced by scholars in sociology, anthropology, psychology, and organization studies, to name a few (Scott 2000). In organization studies, scholars have explored different elements of social networks relative to embeddedness of organizational routines, informal information sharing, holes and bridges in knowledge flow, and the transfer of social norms and tacit knowledge (e.g., Merton 1957; Granovetter 1973; Wellman and Berkowitz 1988; Burt 1992). In IS, social network concepts have been used to study the behaviors of teams, organizations, industries, and ICT-enabled communities (Nohria and Eccles 2000; Barabasi 2003; Monge and Contractor 2003; Christakis and Fowler 2009).

The social network perspective is useful for studying some of the emerging forms of social or organizational arrangements and the roles of ICT (and more recently, social media). A social network is a social structure made up of individuals called "nodes" who are "connected" by an interdependency like friendship, kinship, common interest, financial exchange, and knowledge or prestige. Networks of relations are enacted by sharing of information or resources among nodes (people) via ties between them (their interdependency). These simple concepts continue to offer scholars " …a surprisingly fruitful way to analyze how social formations organize, change, and grow" (Oinas-Kukkonen et al. 2010, p. 62).

Concepts of network analysis such as social capital (as resources derived from networks of relationships) provide a vehicle for examining digitally enabled social networks. For example, Robert et al. (2008) use social capital as the lens to study the differences between lean digital networks and face-to-face interactions. In addition, via emerging computational capabilities, researchers are also enabled to conduct complex network analysis such as ICTs (such as social media) that can enhance interactions across social networks (Agarwal et al. 2008). In this regard, building from the theory and methods of social network analysis, Kane and Alavi (2008) studied how multiple users interact with multiple ICTs within healthcare groups.

5.2.2.4 Social Philosophy

Scholars in IS have drawn on social philosophers to gain insight into contemporary and complicated dimensions of IS design, management, and theory. These dimensions include but are not limited to politics, power, cognition, and rationality of IS (Fitzgerald 1997). The philosophy-oriented conceptual thinking came about in part as a challenge to the conventions of systems rationalism that pervaded much of the early approaches to studying IS. This work also provided a more conceptually nuanced view of the world, shifting attentions from systems and technology to the interplay of people and their complex universe.

Most notably, IS researchers have levered philosophical approaches with a significant input from critical social theorists to address IS sociotechnical problems. Arguably, critical social theory in these studies is mostly rooted in the work of Jurgen Habermas and Michel Foucault. These critical social theorists posit that social structures are not independent of people: they are produced and reproduced by them. And people's ability to transform their social and economic circumstances is constrained by multiple cultural, social, and political forces. To this end, critical research seeks to outline the restrictive dimensions of the status quo and carry forward an emancipatory agenda by focusing on conflicts and contradictions in contemporary society (Myers 1997).

Other IS researchers have drawn on critical social theories to study freedom, social control, and power with regard to the development, use, and role of IT in organizations and society at large. Critical social theory has allowed these researchers to account for ethical and moral aspects of IS, by focusing on emancipatory approaches and the betterment of people's lives (Ngwenyama and Lee 1997). Critical approaches critique taken-for-granted assumptions, directing attention to the potentials of people in changing their social and material circumstances. Germane to this view is the thesis that people who interact with IS need not be constrained by their social circumstances (Orlikowski and Baroudi 1991). As an example, Hirschheim and Klein (1994) applied critical social theory to study IS development. Their critical approach discards oversimplistic notion of users and the dynamics of context by paying attention to how different user groups are affected by system development and may react to it. It also explicates how the system may fit into organizational context and how other organizational dynamics such as power and politics come into play.

While sharing some of the same philosophical roots, recent sociotechnical scholarship has shifted focus from railing against prescriptive IS development methodologies toward a broader view on the roles of ICT in contemporary organizations. In particular, the new sociotechnical approach that emerged in the 1990s is strongly inspired by the broader stock of social science theory (i.e., theories from science and technology studies [STS]) in order to address the multiple substantive issues that are associated with ICT (Dunlop and Kling 1991). These theoretical insights are critical in contrast to the classic sociotechnical approaches that had some distinctive "blind spots" in dealing with rapidly changing contingencies of workplaces and malleable technologies that lend themselves to user improvisation (Malone et al. 1995; Ciborra and Lanzarra 1999).

5.2.3 Science and Technology Studies

Scholars in the intellectual community known as STS* are concerned with the reciprocal relationships among social, political, and cultural structures, science/scientific research, and technological innovation. Scholars of STS bring a broad range of perspectives to focus on the relationships among technology and society. So, historians, communications, sociology, computer science, political science/policy studies, and information studies scholars are found in central roles in STS.

Given the variety of models, conceptual frameworks, and domains of study, there is no agreed upon definition of what constitutes or qualifies as studies of technology within STS (Van House 2003).

* For more about the STS community, see Hackett et al. (2008) and http://www.4sonline.org

This intellectual ambiguity serves STS well as it makes the community open to exploring new technologies. And, by the 1980s, technology studies began to proliferate in STS. Two seminal works on social shaping of technology (SST) (MacKenzie and Wajcman 1985) and the social construction of technological systems (Pinch and Bijker 1987) signaled what Steve Woolgar was to call the "turn to technology" (Woolgar 1991).

Despite its ontological and epistemological heterogeneity, STS scholars pursue common themes. Virtually, all STS researchers are united in their aim to dispense with the predominance of technological determinism. They believe that the simplicity offered by such a perspective fails to recognize the dynamic and complex process through which technologies interact with society (Bijker 1995; Latour 2005). STS researchers also unanimously argue that the "black box of technology" should be opened up for sociological analysis (Law and Bijker 2000). To do so, researchers must pay attention to the process and content of technology itself. Shifting away from "the impact" of technology, this body of research tends to highlight how technology is constructed during research, development, and innovation phases and how structural and political circumstances of its development are reflected in technology. Over time, STS scholars have embraced several theoretical approaches. Three of the most prominent are the social construction of technology (SCOT), focusing on constructs like interpretive flexibility and relevant actors; the SST drawing on concepts like configuration and trajectories; and actor–network theory (ANT) that introduces networks, enrollment, translation, and irreversibility.

5.2.3.1 Social Construction of Technology and Social Shaping of Technology

As the name implies, SCOT conceptualizes technology as not determining human action: humans socially construct technology (Bijker 1997). Social constructionists, the advocates of SCOT, downplay self-evident explanations of effects stemming from the material attributes of a technology: constraining and enabling effects of technologies are matters of interpretative practices of people in the social context. The process through which technology is constructed is described through a number of stages. The first stage involves the concept of interpretive flexibility to explain how a technology is socially constructed. The second stage explains how technology reaches stabilization, a state where the "relevant social groups" have their problems resolved and desires manifested in the artifact. In the final stage, the technological content of the artifact is linked to the social, through considering the meanings that are assigned to the artifact by the relevant social groups: it comes to "closure."

The conceptual pillars of SCOT are found in a number of IS studies. One example is Orlikowski and Gash's (1994) study of people's interpretation of Lotus Notes. Building on Bijker's (1987) conception of "technological frames," their study stressed the specific uses to which the technology is put in a given setting and how the context of use influences the users' interaction with the IS. The lack of uniformity among the technological frames of disparate social groups is also attributed to the fact that "technologies are social artifacts, their material form and function will embody their sponsors' and developers' objectives, values and interests, and knowledge of that technology" (Orlikowski and Gash 1994).

Some scholars see SCOT's notion of closure as privileging design over use as this diminishes the recurrent reinterpretations of technological artifacts by different groups of users (Wajcman 2000). In response, STS scholars advanced the SST perspective. The SST perspective shares many commonalties with SCOT but avoids the problems that lead SCOT theorists to implicitly assume that technological structures will become something external to human actions during use. This noted, early SST work was rebutted for giving undue attentions to technology developers and technology design (Russell 1986).

Through a number of revisions, SST researchers (notably Russell and Williams 2002) fine-tuned their theorization to open up the concept of design and development, portraying technology development as an open and indeterminate activity, through concepts like "innofusion" and "configuration." Innofusion is the process through which innovation extends to implementation, consumption, and use (Fleck 1988). The technological artifact emerges and remerges "through a complex process of action and interaction between heterogeneous players"—what Fleck calls "learning by trying" (Fleck 1994). Along the same line, "configuration" advances the notion of open design and implementation,

by appealing to technology in cases where a constellation of heterogeneous components is locally incorporated into some kind of working orders. In this sense, technology developers only preconfigure their products, which later become subject to various reconfigurations in the local site of use (Williams 2000).

The "strong constructivism" that underpins both SCOT and SST however, can lead analysts to discount any trace of, or role for, technological agency. Hutchby (2001, p. 450) argues strong constructivist approaches showcase "… humans are capable of interpreting the capacities of technologies [such as a bridge or an airplane] in varying ways." But strong constructivists do not address the central question of "… does the aeroplane lend itself to the same set of possible interpretations as the bridge; and if not, why not?" (Hutchby 2001, p. 447).

5.2.3.2 Actor–Network Theory

In contesting technological determinism, both SCOT and SST have been accused of falling into a form of social determinism: overstressing social choice at the expense of technological considerations. By contrast, ANT seeks to avoid determinism. While ANT shares with social constructivists the central premise that social structures and practices cannot be realized solely through an account of the material properties of technologies, ANT distances itself from social determinism by making no analytical distinction between the social and technical (Latour 1987, 1999). Rooted in a "… ruthless application of semiotics" (Latour 1999, p. 3), ANT's first premise is that entities have no inherent qualities: they acquire their form and functionality only through their relations with other entities.*

The second premise of ANT is "symmetry" among humans and technological artifacts, arguing against any *a priori* distinction between what is technical and what is not (Bloomfield and Vurdubakis 1997). As Latour (1991, p. 129) maintains: "… rather than assuming that we are dealing with two separate, but related, ontological domains—technology and organizations—we propose to regard them as but phases of the same essential action." Building from the concept of symmetry, both technological and social entities are explained as "actants" (Akrich 1992).

An actor–network is constructed through the enrollment of actants (both human and nonhuman actants) into a network of relations by means of negotiations. This process is explicated by the "sociology of translation" that aims to describe, rather than explain, the transitions and negations that take place as the network is configured or "translated" (Callon 1986). The translation process is political in nature and begins with a certain "problematization" when one actor identifies a problem that is shared by others and starts to convince other actors that the problem is significant enough to dedicate resources for its solutions.

Actor–networks reach stability when they become irreversible. Irreversibility is when it would be either too costly to reverse the relationships or doing so becomes improbable. Reaching network stability requires (1) successfully negotiating the enrollment of participants, followed by the (2) translation of an (3) obligatory passage point (when the sets of relations and those enrolled become (4) irreversible) (Latour 1987). Mobilization of network members ensues as a result of irreversibility and stability where social investment in the network reaches a point at which withdrawal would be unthinkable. The durability of a network is a matter of the robustness of the translation. Networks collapse or undergo changes if the translation processes that brought the networks to their current state can revert or if the networks cannot resist alternative translations.

To date, ANT's conceptual vocabulary and methodological demands have been used eclectically in IS research (Walsham 1997; e.g., Pouloudi and Whitley 2000). Numerous case studies inspired by ANT serve as a means to improve the understanding of IS researchers of the design and use of ICT, which is of

* One implication of this relational premise is that concepts of context cannot be distinct from an actor–network—what one might characterize as "context" or "aspects of the situation" matter in ANT only if there is a relationship developed among entities of interest. That is, ANT is neither contextual nor a-contextual: the actor–network is both local and distant and the relationships between entities of interest, action, and location are the focus.

significance for IS (Hanseth et al. 2004). And there exists a prominent and meticulous adoption of ANT in the literature on information infrastructure. The size and complexity of infrastructural technologies such as groupware, and the characteristic that they generally build upon existing technologies, make researchers direct their focus from ICT or isolated technological artifacts to a more complex notion of IT infrastructure (Hanseth et al. 1996). Several researchers have drawn upon ANT to account for the sociotechnical nature of the information infrastructure, which includes not only artifact but also human habits, norms, and roles that may prove its most intractable elements (Jackson et al. 2007). For example, building on ANT's conceptual vocabulary, Hanseth et al. (1996) investigate how any given elements of information infrastructure constrain others and how these elements inscribe certain patterns of use. To do so, they identify explicit anticipations of use by various actors during use and the way these anticipations are translated and inscribed into standards.

5.3 Contemporary Sociotechnical Theories

There has been, over the past 15 years, substantial sociotechnical theorizing. Many of these contemporary approaches to sociotechnical theorizing draw together concepts from several of these sociotechnical sources and combine both empirical and theoretical works to advance sociotechnical thinking, as we outline later.

5.3.1 Genres

The concept of "genre of organizational communication" was introduced to examine organizational communication with a particular focus on the mediating role of communicative technologies. Rooted in ancient Greek word, *genos*, genre denotes races, kinds, and classes (Zimmerman 1994). The academic use perhaps dates back to the 1950s and these early formulations were mostly taxonomy oriented, seeking to classify the form and content of written and spoken communicative actions. Contemporary efforts have shifted toward the classification of communicative or rhetorical practices (Østerlund 2007).

Yates and Orlikowski (1992), building on Millers (1984), define a genre as "… a typified communicative action invoked in response to a recurrent situation" (p. 301). The recurrent situation encompasses the history and nature of established practices, social relations, and communication media within organizations. In this view, genres are meaningless without the daily practices into which they are situated. Central to this theorization of genres is a focus on community. That is, the communicative purpose of a genre has to be shared within a community (i.e., organization) by more than one person.

The structural features, communicative technologies, and symbol systems of a genre are all made sense of within the community (Yates and Orlikowski 1992). For example, an e-mail is not an instance of communicative genres, while a memo or a meeting agenda, which may be mediated by the use of e-mail, is (Päivärinta 2001). With this distinction, genre theory dispenses with information richness theory, which defines a medium rich or lean due to its intrinsic characteristics. Based on genre theory, the same communicative medium can convey messages using different genres, just as the same genre can ensue using different communicative media. For instance, e-mail can carry messages in the form of business letter or informal personal notes that are essentially considered disparate forms of genres (Lee 1994). Genres are dynamic: introducing and using a new medium may transform daily practices and changing communication practices. For example, Davidson (2000) examined how computerized clinical order system changed interactions among multiple groups of organizational actors (e.g., physicians, nurses, and pharmacists).

5.3.2 Boundary Objects

A boundary object is something that is simultaneously "rigid" enough to be commonly understood among different social worlds and "plastic" enough to be understood within each social world (Star 1989;

Star and Griesemer 1989). Some scholars have focused on how ICTs serve as boundary objects among different groups (Fleischmann 2006a,b; Gal et al. 2008). Others have focused on the negotiations that occur around boundary objects (Lee 2007; Lutters and Ackerman 2007; Rajao and Hayes 2012). Still others have focused on how ICTs, acting as boundary objects, facilitate the flow of information in collaborative work (Osterlund and Boland 2009; Tyworth et al. 2012). Still others have focused on how to design ICT to function as effective boundary objects (Akoumianakis et al. 2011).

5.3.3 Biographies of Artifacts

The biographies of artifacts (BoA) approach has emerged from the work of a small group of scholars at Edinburgh University (Pollock et al. 2003). Building on the series of deep studies of various broad-scale commercial technologies, the BoA conceptualization is that an ICT or an IS often exists at one or more places (installed in more than one location) and varies by both the version (temporal) and the location (spatial). To understand and study such diverse, distributed, and popular (or common) IS requires one to pursue a biographical approach to analysis, one that focuses on the evolution of the particular artifact over time, its changes and evolution based on uses and events at various sites, and the players in these various arenas (Pollock et al. 2003). Building, as it does, from the SST tradition and from cultural studies (where the BoA concept first emerged), BoA provides a framework to approach large-scale technological analysis. Its emphasis on trajectories and social shaping, and the demands of maintaining a dual focus—on both common events and unique events, as both can shape the direction of the artifact's evolution—make it a demanding approach at present (e.g., Pollock and Williams 2009).

5.3.4 Domestication

The domestication of ICTs is premised on the processes of consumption and focuses on the ways in which a new artifact, concept, or object of interest is brought into an existing social world (Berker et al. 2006). Consumption is more than use as it encompasses the mutual adaptations of social structures, processes, and meanings as people bring the object of interest into their world and learn to live with it (or not). Much of the original domestication scholarship focused on the take-up and uses of the media and digital technologies in the home (Silverstone and Haddon 1996). Domestication scholars broadened their focus of inquiry and the conceptual approach soon could be found in IS (e.g., Frissen 2000).

Domestication focuses attention to the ongoing and mutually adaptive processes of bringing ICTs into existing social worlds (often the home or people's lives). Domestication scholars see ICTs as arriving with preformed meanings constructed by advertising, design features, and both informal discourse (e.g., word-of-mouth and personal networks) and formal media messages. Once acquired individuals invest the ICT with their own significance, create and adapt strategies to manage, use, and value these, and deal with the changes their presence, uses, and meanings entail (e.g., Stewart 2003). Haddon (2006) makes clear domestication focus on consumption, rather than use, highlights processes of negotiation in bringing ICT into the social world. This process of making something (like a commodity technology or a particular artifact) personal is a "taming" or training that takes place over time. This may not lead to success (or a desired outcome) and domestication scholarship often highlights the churning or seemingly cyclical patterns of nonprogress toward full acceptance/belonging. In focusing on this process, domestication emphasizes the relationships among the object, individuals, and the larger social milieu in which this process unfolds (and often grants agency to the media messages and opinion leaders for framing the roles, uses, and expectations of ICT).

5.3.5 Computerization Movements

The computerization movements approach extends concepts of social movements in two ways. A social movement, broadly defined, is coordinated collective action that relies on informal social units to

pursue institution building toward shared goals. These goals can either be aimed at a specific and narrow policy or be more broadly aimed at cultural change. Often this institution building creates conflict with existing institutions. Institution building requires leaders, visions, resources, followers, and events. Adapting this broad area of sociological inquiry, Kling and Iacono (1988) articulated a computerization movement as a specific form of social movement, one focused on institutionalizing a particular ICT or IS. Moreover, a computerization movement emphasizes the public discourses around a new ICT, the ways in which various adherents and opponents frame the computerization efforts, and the practices through which these frames and discourses unfold. Elliott and Kraemer (2008) compiled a volume of computerization studies as a tribute to the late Rob Kling. Hara and Rosenbaum (2008) have extended computerization movements, developing a typology based on an empirical analysis of published work in this area.

5.3.6 Sociomateriality

Derived in part from the sociology of science, sociomateriality posits social practices as intrinsically conjoined with material things—and for our interests, this tends to focus on the material aspects of ICT and IS (Orlikowski and Scott 2008). Sociomateriality does not assign agency to people or technology but views the social and technological to be ontologically inseparable (Suchman 2007). It hence provides a means for understanding how social meanings and technological actions are inextricably related and, together, shape social practices.

The sociomaterial perspective considers knowledge to be enacted—every day and over time—in and through people's practices. Practices are "… recurrent, materially bounded and situated action engaged in by members of a community" (Orlikowski 2002, p. 256). Sociomaterial scholars treat knowledge and practice as mutually constitutive: knowing is inseparable from knowledge practices and is constituted through those actions. Central to this view is the thesis that technological affordances are achieved in practice and can only be understood by focusing on their material performance that is always enacted by humans. In this way, the performativity of ICT and IS is not given *a priori*; they are temporally emergent and enacted (Orlikowski and Scott 2008).

5.3.7 Social Informatics, Social Actors, and Sociotechnical Interaction Networks

Inspired by constructivist approaches to studying technology found in STS and sociology, social informatics (SI) is particularly concerned with computerization movements: The transformation of human social arrangements and activities that follows from the implementation, use, and adoption of computers in different types of organizations and social systems (Horton et al. 2005). SI is a perspective, a way of framing, the particular dynamics of IS and ICT in social and organizational worlds. SI scholars seek to theorize ICT and IS as evolving crystallizations of interests, activities, structures, and artifacts that are constructed over time in response to local and institutional conditions (Davenport 2008).

SI scholarship arose in response to the research in computer science's failure to adequately explain or even examine the changes in social structures and organizational processes that arise as new ICT and IS are taken up and used. Kling (2007) notes that SI is "a body of research that examines the social aspects of computerization". A more formal definition is "the interdisciplinary study of the design(s), uses, and consequences of information technology that takes into account their interaction with institutional and cultural contexts."

Kling is recognized as the foremost proponent of SI during his lifetime (Day 2007) and hailed as the man who "brought computing and sociology together" (Wellman and Hiltz 2004). Kling, as a prominent member of a research group at the University of California, Irvine, began to explore IS in local government across the United States in the early 1970s. Soon, Kling and Scacchi (1982) developed an explanatory framework, "the web of computing," in which they asserted that organizational computing

must be viewed as an ensemble of equipment, applications, and techniques with identifiable information processing capabilities. This ensemble or web stands as an alternative to "engineering models" that focused on the technological equipment and their information processing capabilities.

As part of the perspective, SI scholars have advanced a set of findings: insights drawn from many studies that, together, can be taken as common or expected outcomes from any computerization effort (see Kling 1996; Kling et al. 2005). First, the uses of any ICT lead to multiple and sometimes paradoxical effects. Second, the uses of ICT shape thought and action in ways that benefit some groups more than others. The design, development, and uses of ICT will reshape access in unequal and often ill-considered ways. Third, the differential effects of the design, implementation, and uses of ICT often have moral and ethical consequences. This finding is so often (re)discovered in studies across the entire spectrum of ICT, and across various levels of analysis, that ignorance of this point borders on professional naiveté. Fourth, the design, implementation, and uses of ICT have reciprocal relationships with the larger social context: it is not possible to isolate an ICT or its effects. Finally, effects of ICT will vary by the level of analysis, making it appear as if there are different phenomena at work across these levels.

Two characteristics of SI distinguish it from the broader sociotechnical research literature. First, SI provides an intellectual framework that can guide methodological practices of IS researchers, one focusing specifically on ICT (and not more generically on "technology"). In the "web of computing" paper (Kling and Scacchi 1982) and later work, Kling (1987) presented IS researchers with a methodological guide for studying institutional uses of ICTs with a focus on the institutional level. A second differentiating characteristic of SI is the greater level of agency provided to the ICT and IS. This stands in contrast to the more common strong constructivism found in SST and SCOT, where technical capacities are not fixed but essentially indeterminate and open to interpretive flexibility (for an overview of this debate, see Grint and Woolgar 1992; Kling 1992a,b).

The social aspects of the web of computing were advanced by Lamb and Kling (2003). They emphasized that the focus on workers and others as users diminished their larger and more complex roles as "social actors" and that only a portion (and often a remarkably small portion) of one's work is as a user. The social actor model further articulated several important social relations relative to the ways in which ICT and IS are taken up and brought into the social worlds of these actors (e.g., Rowlands 2009).

Several SI scholars have also extended the web of computing model, advancing sociotechnical interaction networks (STIN) as a more fully developed version (Kling et al. 2003). Inspired by the symmetrical treatment of humans and nonhumans in ANT, Kling defines STIN as a network that "includes people (also organizations), equipment, data, diverse resources (money, skill, and status), documents and messages, legal arrangements and enforcement mechanisms, and resource flows" (Kling et al. 2003, p. 48). STIN distinguishes itself from ANT's conceptual and abstract vocabulary by providing a methodological heuristic for identifying the network's members and boundaries (e.g., Meyer 2006).

5.4 Emerging Scholarly Spaces

Beyond the substantial intellectual activity surrounding the development and conceptual advances in contemporary sociotechnical theorizing as described in Section 5.3, we provide an overview of two emerging scholarly spaces—multidimensional networks and economic sociology—whose members are focusing on the roles of ICT and are reaching out to sociotechnical scholars for guidance. The first space reflects a subcommunity of social network scholars who are grappling with the empirical and conceptual issues of various ICTs being involved in or interacting with people's social networks. The second space is a distinct intellectual subcommunity that is generating attention in both economics and sociology.

5.4.1 Multidimensional Networks

Many scholars are drawing on concepts from social networks to study the roles and effects of ICTs in social and organizational life. Relative to this, two major views coexist. In the first view, ICT is

considered an exogenous variable that can shape social networks. For example, the work of scholars like Barry Wellman and colleagues has investigated how ICTs can substitute for communication networks and how it can reconfigure these human-centric relationships (i.e., Wellman and Gulia 1999; Wellman 2001; Wellman and Haythornthwaite 2002).

Recently, a second view on the role of ICTs in social networks is emerging. This view rejects any separation between ICT and the network, treating ICT as an endogenous variable (e.g., Monge and Contractor 2003). These scholars advance the concept of a multidimensional network to help researchers capture the entangled and multifaceted relationships between individuals and technologies. By definition, multidimensional network is both multimodal and multiplex. Multimodal networks contain nodes of different types, and multiplex networks are comprised of multiple types of relationships among nodes (Contractor et al. 2011).* These simple concepts help sociotechnical researchers focus on the structure and dynamics of networks involving different types of players (people and technology) and different types of relations among multiple people and technologies.

5.4.2 Economic Sociology

Economic sociology has emerged in the past 20 years as an intellectual community that focuses attention to the socially embedded nature of economic activity (see Swedberg 1994). Social embeddedness is at the core of economics sociology and has three characteristics. First, an economic transaction is done by and for people. As such, this transaction reflects sociality in the ways it is conducted, in the sets of assumptions regarding the behaviors of the participants (and the behaviors of the nonparticipants), and the roles that these transactions play in the larger social world (their structuring potential). A second characteristic is that the motives of the participants are influenced by their social relations, norms, and structures: participants are social agents (e.g., Swedberg and Granovetter 2001). In this rejection of "homo-economicus," economic sociologists go beyond Simon's concepts of satisficing and reflect the fundamentals of bias, anchoring, and attention to social activity that Tversky and Kahneman (1974) theorized on in their Nobel-winning prospect theory. The third characteristic of economic sociology is the importance of institutions and their construction as sets of shared interests and social relations that are so important to the structuring of society that these interests and relations are often encoded as laws and regulating social norms (e.g., Rauch and Casella 2001).

The empirical and conceptual premise of economic sociology is being advanced by economists, sociologists, and political scientists. However, they have, collectively, done little to conceptualize the roles or effects of ICT. That is, the roles of ICT as both a participant in economic life and social life, and the potential effects of the presence and uses of ICT on social relations and social structure, remain anomalous. With this noted, there has been some recent work to advance the role of technology (more broadly) in economic life by building on the flexible conceptualizations of technological materiality (e.g., Pinch and Swedberg 2008).

5.5 Conceptualizing the ICT Artifact

We began this chapter by noting that IS scholarship focuses on the relationships among ICT and organizational actions, processes, structures, and changes (Leavitt and Whisler 1958; Markus and Robey 1988; Benbasat and Zmud 2003; Sidorova et al. 2008). As these scholars and others have noted, conceptualizing the ICT artifact, IS more broadly, and their effects remains both a core mission and a difficult task for IS

* This discourse has similarities with the sociomateriality discussion (Section 5.3.5). The most distinctive difference between the two is the explicit embedding of a technological artifact into a network of social relationships that multimodal networks demand. Concepts of networks and embedding may also hearken ANT. But the multimodal conceptualizations are not premised on the conceptual foundations of symmetry, enrolment, negotiation, translation, and irreversibility on which ANT relies.

scholars (Orlikowski and Iacono 2001; King 2011). As we have outlined here, the sociotechnical perspective and its underlying premises provide IS scholars with a range of conceptual tools to advance our empirical bases, theoretical understanding, and design interventions relative to IS in organizations and society.

At the core of the sociotechnical perspective are (1) the characterization of ICT and IS and (2) the conceptual focus on technological agency. Relative to the characterization of ICT and IS, sociotechnical approaches provide a range of conceptualizations: the strong social constructionism of SCOT, the more limited social constructionism of SST, the conceptual symmetry of ANT, and the weaker constructionism of STIN and sociomateriality. Relative to technological agency, sociotechnical approaches from this are mutually interdependent with social and organizational aspects of the situated phenomena. This provides a useful alternative to both the standard models of IS and other emerging approaches seen in IS.

Over the past decade, scholars have begun advancing design science and design theory as another approach to IS research (e.g., Gregor 2002; Pries-Heje and Baskerville 2008). Given the design focus and interventionist orientation of the Tavistock traditions of sociotechnical research, it may be that design research is one vehicle for sociotechnical scholars to pursue (e.g., Markus et al. 2002; Baskerville and Pries-Heje 2010). More generally, given the broad scope of IS scholar's research interests and the equally broad range of conceptual approaches taken, the sociotechnical perspective provides a set of conceptual tools and empirical insights to advance the state of IS research (King 2011; Sawyer and Winter 2011). That is, sociotechnical approaches to studying ICT and IS provide useful intellectual guidance to advance our theorizing on technological artifacts and how people's work practices and organizational arrangements are afforded by technological resources and inhibited by technological constraints.

Acknowledgments

Thanks to Brian Butler, Sean Goggins, and Heikki Topi for their comments on earlier versions of this chapter. Thanks to students of the Syracuse iSchool's "sociotech reading group," and particularly Gabe Mugar, Matt Willis, Andreas Kuehn, and Janet Marsden, for comments and questions on formative parts of the work presented here.

IT and Global Development

Erkki Sutinen
University of Eastern Finland

6.1 Introduction

The increasing role of information technology (IT) in global development has a fascinating history, especially from the viewpoint of information systems (IS). In the following, we will briefly follow two parallel threads. The first one has transformed the interpretation of the concept of global development from a set of universal indicators to the one emphasizing local potential and strengths, conceptualized as the term of bottom of the pyramid. The other thread portrays the changing self-image of IS from that of analyzing the efficiency of a given information system from the perspective of the surrounding business or governance structure toward one that makes a positive change in the surrounding societal, even global, context.

Interestingly, the two threads have recently encountered each other at the crossroads of IT that—as an artifact—has remained the commonly accepted (although also widely debated, see Chapter 1) research focus for the discipline of IS.

The definition of global development depends on the factors that are used to measure it. In addition to the economically oriented gross national product, indicators such as human development index (HDI) that measures the level of well-being, based on factors such as education, life expectancy, and standard of living (Human Development Reports, 2012), are also used. In addition to objective approaches based on government statistics, interview-based barometers address development from the viewpoint of individual, subjective experiences, such as the World Happiness Report (Word Happiness Report, 2012) by researchers from Columbia University.

HDI and WHR are examples of indices that measure the development from a human perspective. Sustainable development, however, takes also into account the environmental aspect. Encyclopedia of Earth (2012) as a member-administered website shows the manifold of ecologically oriented indicators for sustainable development.

Indicators and definitions are keys for analyzing the pace of global development. However, the crucial challenge is to make development take place. This requires setting goals of which the UN-defined Millennium Development Goals (2012) are the best known at the moment. The recent Rio + 20 Conference promoted the process toward sustainable development goals.

Complementary to the needs-focused MDGs, the bottom-of-the-pyramid approach (Prahalad, 2004) emphasizes the potential of the poor communities as a consuming market as well as a producer. This is a particularly interesting viewpoint from the IS perspective, since one of the main products for poor communities are mobile services—which also can market the communities' own production to the global markets.

The other thread, parallel to the emerging theme and variations of global development, is the redefining scope of IS as a discipline. As coarse, objective and global development indicators are fabricated into more focused and detailed ones for limited contexts, to achieve better accuracy, IS research is getting more focused on improving the life of an individual user or a user community. For example, the generalizability of research outcomes seems to give way for their transferability, from one user or context to another one.

The traditional agenda of IS research has been to improve business and governance processes by technology (see, e.g., Nilsson et al., 1999). Over the years, the agenda reduced to analyzing the usability of off-the-shelf solutions in given user scenarios. The research has followed the positivist approach for explaining and predicting the usefulness of technology for the users' performance and applied quantitative methods.

As neat and controlled the laboratory-oriented approach of IS might be, applying the natural science paradigm to the observed human users of technology, the agenda easily leaves IS in a disciplinary isolation, trapped by its own methodological dogmatism. Recently, this trend has been criticized by, for example, Walsham (2012) and Niederman and March (2012). Whereas Walsham calls for an interdisciplinary openness that allows IS to see whether ICTs make the world a better place, Niederman and March argue for a clear role for design science and action research that allows IS research to make a difference for the user communities.

The rebirth of IS as a world changing discipline—that would also inspire young talent and attract research funding—is built on the dual roots of the discipline. American pragmatism by Dewey and others emphasized the complementarity of thought and actions: what works is true. The continental critical theory, dating back to Marx, Nietzsche, and Freud, differentiates what is wrong from what is right. This academic heritage is the background of a discipline for a better, developing world, to be combined with the recent trends in IS research for design science and action research.

What many IS researchers (but not all; see the debates reported in Chapter 1) seem to agree upon is the role of IT artifacts as a focus of IS research. An IT artifact refers not only to a technical implementation, like product, service, application, or system, but can also be a construct, a model, or a method (Niederman and March, 2012). The consensus paves way to the very encounter of global development and IS.

For pragmatically oriented IS research, IT does not remain an observable artifact, but becomes an artifact for innovation. This is where IS meets with the challenges of global development: an innovation changes the existing practices, routines, and processes (Denning and Dunham, 2010). The agenda is also aligned with the expectations of and fears from IT in the context of developing countries. Critical approach is required to distinguish between the threats and opportunities where the affordances and limitations of IT take their users and the surrounding communities, even nations. For instance, the role of SMSs for improved communication is different before and after a revolution. For the oppressed and the ones in power, a simple SMS can carry a completely different meaning—even if the person in question is the same.

The global stage for the encounter of IS and universal development challenges is scaffolded by the recently emerged penetration of mobile technology, especially in the world's poor communities. The poorest one billion people at the bottom of the pyramid are not only using innovations imported from outside, but actively bringing about novel applications for changing their everyday. The potential of the whole new user group is also a crowd for sourcing innovations (Howe, 2006). The innovations from the grassroots might not only be incremental but also radically change the conditions of life. From the organizational learning point of view, we talk about double-loop learning instead of single-loop learning (Argyris and Schön, 1978).

From the viewpoint of an IT user, development always takes place within an immediate, physically or virtually local context. This observation sets the background for the current article. Therefore, rather than portraying the global image of IT users (Dutta and Mia, 2011), we focus on how IS research can develop an ordinary life.

Following the newly emphasized interdisciplinary orientation of IS, we will deliberately move from the IS-centric discussion to the dialogue between IT and global development. This is the *de facto* agenda of the renewing, interdisciplinary IS: to analyze the encounter of people with IT and have technology make a positive change to the lives of these people.

In many ways, the concepts of global development and IT seem slightly outdated from the mainstream of contemporary discussion. Development was on the global agenda at the turn of the millennium when the United Nations accepted the list of Global Development Goals (MDGs), to be reached by 2015. At about the same time, the expectations from IT were at their peak years. Within the cabinets of political decision makers, the challenges of global development and the opportunities of IT are still at the status as high as that of their politically correct promoters, but early adopters and change makers have already chosen alternative paths of uncertainty and new sources of inspiration, as the Arab spring has shown.

The intent of the chapter is to show that when juxtaposed with or cross-fertilizing one another, global development and IT can refresh, if not transform each other. In fact, global development, among other vast challenges of the humankind, offers a particularly interesting call for information technologists. But to comprehend this opportunity, one must go to the roots of both concepts, like for any renaissance.

What does global development mean from the viewpoint of IT? Who is the client of IT solutions that can launch the first step toward positive change and progress that the term development refers to? Is he/she a street kid sleeping in a wasteland next to a five star hotel? Or is he/she a president of a developing country? Or is it an anonymous group of bottom-of-the-pyramid customers that buy airtime for their text messages? From the IT perspective, there is nothing truly global in development, as there are very few, if any, universal solutions to all seven billion people. Development, although global as an abstract phenomenon and challenge, is local in contents and concrete customer requirements. Relatively, a poor community at the outskirts of a rich city may benefit from IT far more than a well-off landowner of a developing countryside. Therefore, rather than global development or a developing country, we will use terms such as *local development* or *developing context*, even a *developing individual*. From the IT perspective, a developing context is a challenge that technology can meet with information.

What, then, is IT from the aspect of a developing context? Customers in a developing context want to improve their lives by relevant, just-in-time, and functional information that requires technology. Far too often, these expectations are latent, unknown to those in the need of information, but likewise to potential solution designers. But when a street kid connects to an online supporter and can get regular food coupons as a text message, he can experience that the information works for him. Or when the president can promote equal access to learning basic literacy and numeracy skills, his/her nation can break the schooling barrier. And when a group of handicapped children in a remote Tanzanian city of Iringa get smart blocks for their rehabilitation (Lund, 2012), the information hits their bodies, not just minds. From the point of view of a developing context, IT is an opportunity beyond expectation.

The whole spectrum of information is relevant for a developing context: the information needs to exceed that of administrational databases or network protocols. Sensory data can be used to analyze

the fertility of a soil or the muscular movements of a child with cerebral palsy; climate information can be refined to expand the knowledge of a small farmer toward that of an expert. In most developing contexts, the technologies should cope with and even make use of uncertain information. The concept of awareness with respect to information can be understood technically as in context-aware applications for unconsciously used data: a mobile device is aware of its user's position and the user does not need to pay attention to that awareness. But awareness can also be used along the tradition of Gestalt therapy, as in tools that promote HIV and AIDS explicit awareness for the user—far from the unconsciousness-related connotation of the term. Digital storytelling, a natural platform for presenting information especially among illiterate users, would even require technologies that convey emotions. The diversity and originality of the demands for IT in developing contexts are indeed apparent already within the concept of information: its types, representation, visualization, and reliability. This starting point provides challenges for IT researchers at the fundamental level of information itself.

Table 6.1 exemplifies state-of-the-art research approaches in the intersection of IT and global development, categorized by the type of the IT artifact studied and whether the motivation is on global development as a challenge or IT as an opportunity. For implementations, or instantiations of constructs, models, and methods, the division between challenge and opportunity loses meaning, because the application-oriented instantiations are based on an explicit challenge, but portray either a design or an analysis (or both) of an IT opportunity that meets with the challenge. The table also illustrates the diversity of the research area. This is why this chapter sketches a scaffold for the research area, based on a conceptualization of computing as a context-oriented discipline.

Classically, computer science has been positioned in the crossroads of mathematics, natural science, and engineering (Wegner, 1976). Methodologically, it has inherited one main principle from each of the scientific parents, namely, abstraction, modeling, and design, respectively. When the area of computing has expanded from strict computer science, computer engineering, and software engineering, the human and social aspects have increasingly gained relevance also in the methods of computing. This has had consequences for identifying user scenarios, developing user experiences, understanding usability issues from a cultural viewpoint, and developing ethical principles for IT (for cultural usability, see, e.g., Kamppuri, 2011). The interplay of the diverse scientific traditions of IT becomes very challenging in developing contexts, which differ significantly from those that computing grew within. For an illiterate farmer, climate information on a mobile platform might be represented as a story. A customer will transform the traditionally Western interpretations of abstraction, modeling, design, and user experience.

TABLE 6.1 Examples of Research Approaches on IT and Global Development by the Type of IT Artifact

Type of IT Artifact	Focus on Global Development as a Challenge	Focus on IT as an Opportunity
Construct	Ethnocomputing (Tedre et al., 2006)	Emergence of ICT4D as a research area (Unwin, 2009)
Model	A posteriori analysis	Future-oriented agenda of IS (Walsham, 2012)
		ICT4D business models (World e-Business Initiative http://www.worldebusiness.org)
Method	Design-reality gap (Heeks, 2002)	Improving mobile interfaces (Medhi et al., 2011)
Implementation	Interventions in application areas such as health, governance, education, agriculture, banking, tourism, business	

With its cross-cutting nature, IT is raising obvious expectations in developing countries. This far, the encounter between global development and IT has taken place in very large-scale projects. The approach goes back to the heroic, hall-of-fame type of understanding of global development and IT. Identify a major problem and attack it with well-trained troops carrying massive weaponry. Typical examples are extensive networking projects, teaching laboratories with hundreds of computers, or national programs for establishing community multimedia centers. A techno hero, trained outside the battlefield, is expected to plan and establish an extensive technical infrastructure to combat ignorance. But ignorance prevails as long as activities or services on the top of the infrastructure are not available. Plain walls or cables do not advance anyone else's progress than that of their constructor's. The projects are mostly funded by massive development aid programs whose benefits are getting more and more controversial and debatable (Moyo, 2009).

Recent concretizations of IT-flavored megaprojects are various programs with a focus on information or knowledge society and innovation; that is, services on the top of the technical infrastructure. The almost miraculous success of the global north, in particular natural resource poor Nordic countries, has been understood to be based on innovative designs and uses of IT. The Nordic road is an attractive progress story that most developing countries want to learn from and adapt to. In essence, national innovation system programs in developing countries aim at a level more advanced than building a plain technical infrastructure: they are building a national system of innovation or a whole knowledge society. While this goal setting looks at the first sight a bit more elaborated than just an extensive setup of material infrastructure, typical components of the innovation system might not take an intended beneficiary, like an individual farmer of a poor community, very far in their concrete development expectations. In order to succeed, incubation or funding services need to address the contents and links to the citizens' everyday life.

Like the devil is told to dwell in details, the challenge of twisting—or, indeed, distorting, see later—IT into a vehicle for progress is in individual encounters, at the very local level, at the bottom or base of the society's pyramid; although, interestingly, a truly networked society has a topology with neither top nor base. The contents and relevance in innovative IT designs for development can only be born at the grassroots.

Interestingly, the metaphors of the current IT streams reflect the ideological change from comprehensive, one-size-fits-all mega solutions toward personalized ones. At the time of ecosystems, cloud services, or grid computing, we are most excited of the individual components vitalizing the systems. Supercomputers do not raise the excitement of ubiquitous technology. In terms of the solutions, the perspective is changing from delivery-oriented electronic malls to piazzas where everyone can set up their small digital apartments, stages, and garages. With facebooks, twitters, and microcredits, individuals can make their expressions known, their chirps heard, and their talents realized. This is exactly what developing contexts need.

Developing communities can make use of IT-based innovations. However, it is essential to distinguish between various genres of innovation. The distinction between aiming at incremental or radical innovations (Henderson and Clark, 1990) has consequences for how IT takes up its role as an agent of change. The traditional mega(lomaniac) approach usually ends at incremental innovation in IT uses. It orients toward conservative changes: users live as earlier but with improvements. Text messages help life, but do not necessarily give value for money in terms of new challenges or alternative jobs. A radical innovation changes the rules of the game, transforms living conditions. A mobile endoscopic surgery unit with specialists consulting from overseas saves lives. A radical innovation, very often, is born in the periphery, behind the infrastructural services and out of the mainstream. We can talk about *pockets of development* by *pocket technologies*, in local and limited contexts.

A radical innovation at the grassroots—"radical" comes from the Latin word radix, for root—makes a creative use of IT as a source of innovation. But individual radical innovations need a way to the mainstream. The recent discussion on innovation emphasizes this dynamics between grassroots and periphery on one side and the mainstream on the other. Open innovation (Hagel and Brown,

2008) refers to facilitating a movement where finding solutions to individual and open challenges can be outsourced to crowds: we talk about crowdsourcing (Howe, 2006). IT offers extensive opportunities for crowdsourcing by giving a face and voice to individuals, independently of their backgrounds. The potential of the young people's energy and fresh ideas can become the radical solution to many of the globe's problems.

One of the main lessons that every foreign expert in a developing context understands sooner or later is that a solution is viable only if it brings benefit to all those engaged in the project or initiative. The principle easily brings about jealousy, misunderstanding, and mistrust, especially in well-funded mega projects. Accusations of corruption or waste of resources start to emerge. However, the whole idea of technology is the benefit for people, and the participatory approach should treat funders, decision makers, designers, and users at an equal basis. At the same time, the nature of the expected benefits might vary significantly between diverse partners and stakeholders. However, demanding benefit for all is a useful starting point for IT development. An individual community in Chiure, northern Mozambique, built their multimedia center with their own money. In order to increase their benefit, they need connectivity, that is, infrastructure. The government will get goodwill for responding to this need. The benefit for all can only happen when all join in the effort, but everyone also gains.

Developing contexts offer several examples, such as mobile banking and e-health, of bending available technology into novel tools that have brought about prosperity and wealth by information and its communication. Whether already success stories or yet weak signals, they challenge IT professionals to familiarize themselves in the dynamics of development, so that they can proactively recognize latent demands for information within developing contexts. Innovative solutions, with their origin in developing contexts, will reshape the field of computing that has far too long become so conventional that IT studies face recruitment problems among the globe's brightest young minds.

6.2 Underlying Principles

This chapter portrays the common ground for a developing context and IT that is designed and used in the context. IT is a cross-cutting technology that has potential to boost diverse areas of a developing society. The contextual challenges may *divert* the face of IT from the image that it is known of in developed countries. We will analyze the diverted image of IT from the four viewpoints of modeling, design, abstraction, and human aspects that we will call *encounter*. Although these perspectives were originally identified to position the discipline of computer science onto the map of sciences, they work well in setting up the stage for IT in a developing context.

In a developing context, the principles of construction and ethnocomputing (Tedre et al., 2006) will shape the four perspectives on computing and, hence, IT artifacts (Figure 6.1). Unlike the mainstream of the ICT4D (ICT for development) (Unwin, 2009) movement that is mostly interested in analyzing the impacts of the transfer of available IT into developing contexts, we take seriously the constructive agenda of computer science (Sutinen and Tedre, 2010). This means that the theoretical emphasis shifts from a conservative and controllable evaluation toward radical and risk taking art of creative design, development, construction, and implementation. A developing context will divert its challenges to artifacts, including products and services that are not yet even dreamed of among the IT users or developers of the global north.

In order to construct, a developer needs to find a comfort zone in his/her workshop. In developing contexts, not only the information technologies but also their related concepts are of alien origin. Similar problems have aroused in other fields, like learning mathematics. A set of ethnosciences or ethnoarts have answered to the question: ethnomathematics, ethnomusic, ethnobotany, and recently ethnocomputing. Whereas ethnomathematics (Gerdes, 2007) is interested in different representations of mathematical concepts, ethnocomputing emphasizes that everyone should be able to enter the world of IT from his/her own background. For example, programming courses

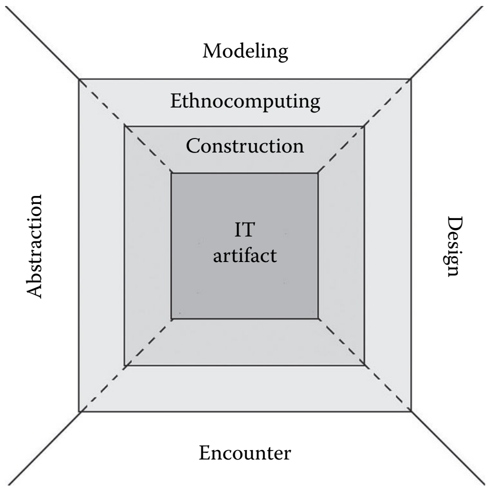

FIGURE 6.1 The four perspectives of computing focus on constructing IT artifacts by ethnocomputing. The ethnocomputing approach ensures that the context tunes the construction process of a relevant IT artifact.

might start from contextually important problems rather than from the conceptology of variables and statements, based on the Western science.

6.2.1 Constructive Modeling in Context

The modeling perspective to IT refers to its roots in natural sciences. The key idea of a model is a set of variables and a function that maps the variables to predict the phenomenon that the model is assumed to portray. In IT, the predicted phenomena cover a wide spectrum of automated processes from the behavior of algorithms up to the user experience of applications. Estimating the performance of an algorithm is an example of a quantitative model, explaining the experience of using, say, a social media platform might require a qualitative approach. For IT artifacts in the developing contexts, the most interesting phenomena to be explained, predicted, or interpreted are the *functionality* and *relevance* of the systems and services in physically, culturally, economically, or politically demanding conditions. Functionality denotes the extent to which the evaluated technology works according to its expectations that can vary throughout the modeling process. Relevance measures issues like the benefit from, added value, cost efficiency, or robustness of, and improved quality of life promoted by the technology in a given context.

Along the lines of modern science education, the empirical paradigm calls for modeling that is a learning process based on observations in the perceived surrounding reality, rather than previously derived, existing theories. The contemporary pedagogical approach is contradictory to the earlier one where a lesson started from the teacher's solo introduction to a theory that the students needed to learn by heart; the students' own activities with applications and examples were secondary to the teacher's presentation. The old approach believes in localizing the commonly approved standards in students' minds, the modern one in students building their own insights from their own observations. When measuring the learning outcomes, the first approach emphasizes global standards, the latter the contextual relevance of what has been learnt.

Often, the transfer of information technologies to a developing context is analogous to the outdated pedagogical model. Technologists seem to believe largely in massifying, delivering, or generalizing the so-called best practices: technologies that have shown to work in a similar context are assumed to be ready for others to adapt to, or learn from. This understanding materializes in countless seminars, workshops, conferences, and courses that call policy makers to learn by heart IT systems, services, or solutions that have shown to be functional or relevant by the models developed elsewhere. One of the

key ideas of computing—modeling, that is, building a model—has been replaced by imitating, that is, following the given model.

In fact, an empirical learning process sets the foundation for a process of building a contextual model for understanding the functionality and relevance of a given IT in a given context. In essence, an empirical modeling process always involves trial and error: the measures to understand the functionality and relevance of the technology are iterated by the feedback from the context. The iterative modeling process goes hand in hand with its parallel of *participatory design*. Whereas the design process results in artifacts, also in iteration, the modeling process iterates the criteria against which the functionality and relevance of the artifacts are measured. The variables determining the functionality and relevance of the technology vary from context to context. Hence, the criteria for functionality and relevance cannot be given beforehand, or standardized. For example, a mobile climate service for a user group of illiterate farmers in an electricity-secure context requires criteria different from those of a similar service to industrial farmers in extremely remote places: the criteria for both functionality and relevance are different.

The analysis mentioned earlier shows that the modeling process is a natural part of the construction of an IT in a given, developing context. It allows developers to tackle real challenges by making use of the opportunities of IT in a bottom-up, empirical, organic way. The modeling process turns feedback from observations into criteria for improving the functionality and relevance of the systems and services to be designed.

Somewhat surprisingly, robotics gives an opportunity to derive a potential user's own understanding of a computational process in a concrete way in a developing context. For instance, Lego robots have been used in IT education to promote self-confidence with technology. Programming robots opens the black box of IT in a way that sparks the creativity of local designers (Sutinen and Vesisenaho, 2006).

Quality assurance is a standard part of the modern design and construction process of an IT system or service. However, in many cases a certified production process is only assessed by superficial quantitative factors or, even worse, by the outcomes that are called performance indicators. For example, in an educational process a certified primary schooling process might count the percentage of children that have taken IT lessons at school, but pay no attention to the competences they have at the time of graduation, or the way they are using computers 1 year after finishing the school. The quality assurance factors and indicators are normally set before the process, thus resembling the outdated theory-driven science education approach.

The definition of quality as the relevance of the contents (Machili, 2012) shifts the focus from the process to the contents at its each step. While the empirically derived, emerging model of an IT system or service focuses on functionality and relevance issues, each modeling iteration improves the quality of the system or service as understood as the relevance of the contents of the system or service.

Modeling answers to the question "Why does a system or service function in a relevant way?" "Why" is also the main question of any natural science inquiry to the observed phenomena in the surrounding physical world.

6.2.2 Constructive Design in Context

The design approach in computing stems from the engineering legacy of the discipline. In developing contexts, engineers have typically been invited as constructors and builders implementing designs that have their origins outside the context. Hence, from the design point of view, engineering has been neither constructive nor contextual. This applies also to most IT systems and services, with exceptions like mobile banking where Kenya is among the global pioneers of novel designs.

Participatory design is a movement within design that calls for ordinary users to join a design process. Culturally, the approach is of Nordic origin: it is a design incarnation of the political egalitarianism of the Nordic countries. In this approach, participation does not separate designers from the rest of the society into an own class of ivory tower experts, but invites them to learn from and struggle with laymen

for innovative designs. Participatory design can also be understood as a consumer movement: consumers are seen the best experts of not only the everyday realities but also the criteria for the functionality and relevance of the solutions to be designed. As a bottom-up or base-of-the pyramid-up movement, we can call participatory design *contextualized* or *contextualizing design*.

The inherent dilemma of participatory design—obvious particularly in developing contexts—is that the users are not aware of the opportunities of technology and for this or other reasons do not have imagination for novel, out-of-everyday designs. This is also reflected in Steve Jobs's comment that radical designs can never be achieved by listening to users' needs. This is certainly true if the users' imagination is not empowered. But designers can also be intellectually lazy or tied to their own ethnocentrism. A latent obstacle making designers reserved for a contextualized approach is the common attitude that developing contexts should use affordable and tested second-hand technologies. This attitude is based on the understanding that every technology has its predestined sequence of steps that every culture should go through. Hence, typewriters should be used before text processing, landline telephones before mobile phones, dull phones before smart phones, and smart phones ahead of tablets. As we know of several examples of developing contexts leapfrogging the predestined steps, the idea of predetermined sequences of technical developments does not hold.

Because of the challenges described previously, participatory design requires close dialogue between professional and laymen designers, as to discover the latent demands for relevant designs and to match them with the opportunities that the advancing, not-yet-available or not-yet-designed technology provides. A design dialogue is a reciprocal learning process between the professionals and the laymen. The professionals need to learn the resources and requirements of the future users of the to-be-designed technologies. The laymen have to learn the principles of technology and get hands-on experience with it to the extent that they can use their imagination to ideate what is possible. A fundamental prerequisite for a mutual learning process—that might take several years—is trust among the professional and laymen designers, because the users might be shy to explicate their still very vague ideas. A fast and politically correct exchange of system specification forms is but a remote image of a committed dialogue for sustainable designs.

One of the ancestors of the participatory or contextual design approach is the Bauhaus movement from the Germany of the 1920s. The Bauhaus movement was a counter reaction to the success story of industrial design of the contemporary England. As a movement, Bauhaus emphasized interdisciplinary and explorative design communities for functional solutions. A concurrent parallel of the Bauhaus communities are living laboratories that accommodate technology developers to implement and analyze a design process *in situ*, within a real-life context. As their best, living laboratories are pockets of development that radiate their successes and enthusiasm to the surrounding region that—particularly now at the time of social media—might easily extend its physical limitations. A living laboratory might be a street studio that gathers street vendors to share the ideas of their business strategies with designers that are creating context-aware applications to city dwellers. A creative design milieu is an environment that features the characteristics for a novel and fresh design.

Unlike the bottom-up approach to constructive design in context, many international development aid funders are stuck in the outdated top-down ideology, leading to strictly hierarchical planning. The planning scheme with its follow-up monitoring mechanisms is called the *logical framework* (AusGuideline, 2005), logframe for short, and it is, in theory, based on a temporal logic model for understanding the dependencies between various components of a project. While the logframe can be used for projects that follow a linear sequence of predefined steps, like those of building a house, it is unsuitable for bottom-up technology design projects with—hopefully—several simultaneous and unexpected inventions, stages, and iterations. The many simultaneous threads of a contextual design project make it impossible to represent the project as a hierarchy. Structured as a hierarchy, the logframe does not allow nor support links between the leaves of the tree-typed structure. However, for an innovative design project of an IT artifact, the most exciting opportunities are based on combining components distant from each other.

Despite all its weaknesses, logframe can be used as a structure for planning a technology design project. The reason is that it is closely aligned with needs-based design. An expatriate designer, whether an individual or a group of experts, is tempted to understand a user community from the viewpoint of their assumed hierarchy of needs: the needs hierarchies can be easily identified outside the user community as a desk research exercise or plainly copied from sources like the MDGs. By the logframe approach, the community can easily be imposed by a structure completely unfamiliar to them. The serious shortcoming of the logframe approach is that it does not fit into a reality with a diverted structure, different from but more valid than its Western, hierarchical representation. Indeed, the diversion is in the viewers' eyes: the hierarchical representation might be equally diverted from a viewer representing a developing context as a developing context can seem chaotic to a Western professional designer or planner. In any case, the logframe is unable to accommodate unexpected, emerging threads that a contextual design process is known of. We conclude that as a design tool, the logframe is based on the outdated waterfall model. The modern agile development should replace it especially in the developing contexts.

In essence, participatory design is aligned with the strengths-based rather than needs-based orientation for design expectations. Unlike the needs-based approach based on the undisputable lists of given targets, the strength-based approach starts from the given resources. While the needs-based approach leads to a simplistic and linear design process consisting of a sequence of predetermined steps, the strengths-based approach requires explorative and creative screening of resources that are not included in any given wish list of ideal contents: the resources might be hidden and unexpected. Whereas the needs-based approach is based on the negatively flavored list of what a community does not have, the strength-based approach is positive and based on what is available.

As a constructive design approach in context, the participatory design process makes IT an agent of change in the design community and beyond it. The design process makes its milieu a cradle for fresh designs. Because of its designed products, the cradle starts to attract people from outside. What was a laid back community from the viewpoint of technology has a potential to transform to an origin of truly new technologies.

A properly organized participatory design process is an answer to the How question of constructing functional and relevant IT.

6.2.3 Constructive Abstraction in Context

The role of abstraction as a key approach in computing goes back to the mathematical roots of the discipline. Mathematics forms the foundation of any automation and is seen in the formal representation and language of computational processes, and the interrelations and functional dependencies of the formal entities. While many of the formal structures of computing, such as database theory, live their own, independent mathematical life, they originate in the real world problems and their formal representation, like that of occupying flights or arranging a census. As a reminder of their real-life background, formal structures have physically descriptive names such as trees for certain types of data structures or divide and conquer for a class of algorithms.

While modeling and design as threads of computing were almost straightforward to interpret as underlying principles of constructing IT artifacts in a developing context, abstraction requires more elaboration. The most natural approach is to analyze abstraction from the viewpoints of representation and language.

Ethnostudies and ethnoarts, in this case particularly ethnocomputing, refer to the ways that culturally central principles, ideas, or forms of expression have been used as entry points to understanding or practicing a certain field of science or art. Ethnocomputing suggests that the language of computing can be learned from one's own culture, not necessarily following the standard steps of a universal curriculum. In practice, an ethnocomputing approach to learning programming in a developing context can take place by constructing programs for gadgets made of physical blocks. Ron Eglash's monograph

African Fractals (1999) gives an example on how fractal, self-iterative, or recursive expressions repeat in West African architecture and how they can be used in (learning) computing.

Contrary to the common belief, mathematics is not *per se* a discipline of a theoretical or deductive character, at least when created. According to Polya (1957), mathematicians work as inductive experimenters, not deductive theorists, and this should be more transparent in how mathematics is taught. From the viewpoint of abstraction in IT, Polya's message translates to IT explorations, which are inspired also by cultural contexts, along the lines of mathematical adventures by de Guzman (1986).

The idea of abstraction calls for unprejudiced theory and concept formation in the developing contexts earlier unexposed to IT, based on identifying the computational interpretations and formulations of their real-life problems. Coping with tolerance, uncertainty, and diversity, whether in natural languages or cultural representations, can form starting points for indigenous abstraction. In many contexts, storytelling might be an appropriate representation for even the core of computing, like programming.

Indigenous abstraction can serve as a counterattack to the conceptual counterpart of technology transfer, namely, concept transfer. Almost any IT conference in developing countries seems to repeat the global slogans, such as the quest for community multimedia centers or integrating IT in school curricula. While innocent and sometimes even beneficial initiatives in themselves, transferred concepts seldom have carried their original meaning to the audiences of their importers.

Abstraction names and positions the inner mechanics of IT. Thus it generates the navigation or mapping system for IT. Each cultural context might need to (and, indeed, needs to) identify IT using its own representations. Abstraction answers to the What, Where, and When questions related to a technology that needs to be in the comfort zone of its users.

6.2.4 Constructive Encounter in Context

We call the human perspective to computing an *encounter*, to emphasize that the development and use of IT takes place in an encounter that always involves people, whether as intellectuals searching for inventions, nerds enjoying the fascination of computational devices, or ordinary users eager to improve their everyday living.

Much of the research and practice of the users' encounter with IT in developing contexts sees people as objects using the technology. This is called an evaluative approach of ICT4D. The objects need to be understood, their needs analyzed, and IT solutions either modestly bent accordingly or, what happens also in developed countries, the encounter simplified by training the objects to use technologies that are far from their everyday needs and unnecessarily hard to learn and master. Rather than empowering people in their everyday life, the technology makes them its slaves. We call the evaluative view of IT encounter an *objectifying* view of users.

A constructive encounter between IT and its users in their context sees people as subjects who want to influence on their situation and make a difference. It is thus aligned with the participatory design approach. However, instead of engineering solutions, the encounter approach focuses on the *human rights perspective*. It promotes aspects like digital rights, ownership, access, and collaboration within diverse user groups. We call the constructive view of IT encounter a *subjectifying* view of users.

Whereas the objectifying view evaluates the extent to which users can *access* information by technological systems and services, the subjectifying view is interested in the opportunities that people can use technology for creating, delivering, and promoting the full spectrum of information: data, knowledge, and awareness. Access of information is usually identified with digital rights. The latter view emphasizes the *ownership* and sharing of information and tools that allow people to process, generate, elaborate, and modify information. Let us consider an example from the area of e-government. The objectifying view evaluates the e-government services from the perspective of government as a service provider and taxpayers as service users. The subjectifying view is interested in the construction of digital platforms that facilitate the citizens to make their voice heard.

From the human rights perspective, the objectifying view is interested in how human rights set standards to information services and access thereof. Hence, the services are analyzed against the given human rights. According to the subjectifying view, the focus is on how people can use IT to promote human rights, even those yet unheard of. Awareness is of a particular interest to human rights, especially from the viewpoint of a developing context. Awareness has two connotations. Awareness can be unconscious and latent or conscious and explicated. As latent, awareness can be understood as a smooth and transparent access to information, and it is based on human rights in the objectifying sense. Explicated awareness is close to emancipation by information, and thus, it promotes human rights in the subjectifying sense. For instance, an emancipatory HIV and AIDS awareness campaign allows its participants to share their stories of coping with the disease. Interestingly, as awareness, also context has both the unconscious or transparent and explicit or manifest connotations. In order for IT to contribute to the development of a context, the members of the context need to be fully aware of that they belong to it.

As an indication that MDGs are aligned with the objectifying view of IT users, the MDGs do not refer to ICTs promoting human rights while they cover, for example, environmental sustainability and global partnership that can set standards for evaluating IT access from the human rights perspective. The UN declaration of human rights (2012) is equally vague in how IT can promote human rights, see relevant articles 17 (right for one's property), 19 (information), and 21 (public service). In general, in developing contexts IT has a significant role in promoting dialogue between conflictive human rights, for instance, those of environmental awareness and the rights of the owner of a mine (http://en.wikipedia.org/wiki/Human_rights#Human_rights_and_the_environment).

The Arab Spring in 2011 showed that IT is in particular a human rights tool for the young population. The challenge is in how IT can help them to join forces to tackle development challenges in their contexts.

The encounter aspect of IT answers to the Who questions—who, by whom, and whose—of IT.

6.2.5 Toward Life Computing

The underlying principles of IT and global development answer the fundamental challenges of making IT a tool for development: Why does it work (modeling)? How does it work (design)? What works, where and when (abstraction)? Who is the subject of IT (encounter)? The answers set up a scene where a diversity of experts and users make use of observation and measuring instruments for modeling; shared workbench for design, various languages, representations, and navigation tools for multilayered understanding; and refresh their human rights for active encounters. As understood in this way, IT is in the center of human activity for a better world, and it can be called life computing.

6.3 Impact on Practice

Even if the landscape of IT within developing contexts is complex and sporadic, it is easy to observe several instances where it has dramatically changed not only the way the discipline of computing is understood by professionals but also the conditions of its users. An obvious example is the mobile phone revolution among the poor people: people at the grassroots are using technology for everything from getting a job up to making a revolution.

Due to the diversity of IT uses in developing contexts, this section can but portray pockets of the impacts that IT has had on people's lives. The perspective is that of individual technologies, their designers, and users.

6.3.1 Impact on the Discipline

We will go through the foreseen impact of IT and global development on the discipline of computing by the underlying principles of modeling, design, abstraction, and encounter.

Modeling emphasizes the empirical orientation in the context. The interdisciplinary orientation that is required for IT to make a difference in a given context strengthens the role of humanities in the discipline.

Participatory *design* generates unconventional crosses between disciplines. Environmental challenges in developing contexts and the demand for renewable local energy connect IT to forestry. Opportunities of modern endoscopic surgery allow specialized pediatric surgeons to use highly advanced technology even in remote areas: this sets demands for using IT for learning modern surgery in real contexts. IT can support a farming community throughout the lifetime of a crop from purchasing the seeds until selling the harvest: successful mobile service design requires collaboration between meteorology, agriculture, anthropology, sociology, and IT.

In the area of *abstraction*, digital storytelling generates novel representations for IT. The contextual orientation transforms usability toward cultural usability, and replaces the idea of localizing universal services to contextualization that starts from the requirements of a given context.

Encounter emphasizes ethics and an anthropological orientation throughout the discipline. For instance, the anthropological concept of awareness transforms standard user expectations to those promoting the metacognition of the user's behavior. The subjectifying orientation of the actor calls for open platforms, for multiple contributions, on an equal basis. This is foreseen in the open source movement that paved the way to the culture of tweets and micromovies.

The general trend common to all the impacts above leads toward a more contextualized discipline that is capable to absorb inspiration from the challenges. The trend poses requirements for an adaptive and flexible curriculum that interconnects to other disciplines.

6.3.2 Impact on the Profession

We will go through the foreseen impact of IT and global development on the profession of computing by the underlying principles of modeling, design, abstraction, and encounter.

Empirical *modeling* as an integrated thread of a software design and implementation process requires that the criteria for functionality and relevance are iterated throughout the process. This demands that IT professionals are able to replace given criteria lists by those created together with the users.

The participatory *design* projects in developing contexts change the landscape of IT consulting. Emerging areas cover areas like mobile banking, mobile learning, IT for health, and IT education that take place in the context. An IT professional changes from a person supporting available practices by conservative solutions toward a change maker. For example, mobile learning focuses on informal learning settings rather than conventional schooling.

Abstraction calls IT professionals to listen to the local voices at the bottom of the pyramid, instead of following the traditional top-down approach of various needs-lists. IT professionals turn into language experts and need to interpret the hidden demands with novel IT representations.

For *encounter*, IT professionals need to design technologies that promote their users' human rights. These cover applications that support interfaith and intercultural dialogue, conflict resolution, and crisis management. Natural language processing and text tools form key techniques for these applications.

In general, the impact from IT in the context of global development has transformed the IT profession toward diverse job profiles. The competences required from IT professionals reflect increased sensitivity and ethical orientation.

6.4 Research Issues

The impact of IT for global development is still at its infancy. At the same time, IT can significantly gain from novel challenges and solutions within the developing contexts. Therefore, it is crucial that IT is developed within developing contexts where an interdisciplinary and multi-stakeholder collaboration renews and rejuvenates both technology and the development that it shall serve. This means that mere

evaluation of existing technology in various developing contexts is not enough; proactive and engaging design and implementation are required.

In a way, the relation between technology and its users in developing contexts reminds that of digital natives and digital immigrants in other contexts. There is a difference, though: instead of differentiating between *users* from the viewpoint of their technology use history, we can measure the extent to which *technology* itself has been exposed to or rooted in a particular user context. Technology can be either *context native*, that is, born—designed and implemented—in a given context, or *context immigrant*, that is, transferred from its origin to an alien place to serve. Using this terminology, most of the technologies used in developing contexts are context immigrants. The key research challenge is how to design context native IT.

Like the impact on IT discipline and profession, the research challenges can be categorized in modeling, design, abstraction, and encounter. Contrary to the issues of a practical nature, research looks, though, for radical rather than incremental changes. In the area of language learning, an incremental innovation allows students to learn Portuguese by their mobile phones during their holidays in Lisbon. A radical innovation lets Mozambican secondary school students to earn airtime by chatting with students that are becoming teachers in the Portuguese language. The role of radical innovation and creativity is crucial for the research-based creation of context native technology, which can also be called indigenous technology.

Empirical modeling requires that the measures for the functionality and relevance of context native technology be rethought. This results in out-of-box, fresh *models* as criteria for successful technologies. To measure the success of context immigrant technologies, it is normally enough to adjust the weights of the measured variables, like in the case of the mobile Portuguese learning environment those related to the user behavior. A set of completely new variables needs to be introduced for evaluating the functionality and relevance of the user scenarios of children teaching adults from the global south to the global north. To measure the impact of context native technology requires qualitative indicators, and thus, methodologies based on the formative approach, like artifact contests and focus user group barometers.

Strength-based or resource-based *design* of context native technologies can be easily juxtaposed with the needs-based design of context immigrant technologies. On one hand, the first is based on how to use the existing resources in a creative way for matching the demands and expectations of the context; both the resources and the demands need to be explored without prejudices or available lists. Needs-based design, on the other hand, makes use of existing, straightforward lists of what is lacking. Research on creative design milieu is an example of a task that results in context native technologies. This requires designing a relevant IT curriculum for the particular developing context.

From the perspective of *abstraction*, research in non-linear information representations and non-structured media is of a particular importance for context native technologies. In a developing context, digital storytelling requires workbenches and studios for diverted stories. An interesting trade-off takes place between abstraction and concretization: a multilayered representation supports both of them.

As of the research for enriching the *encounters* between users and their context native technologies, a completely new research area in the intersection of human rights and information technologies is envisaged. The key question is how IT can promote human rights by strengthening the ownership in information in all its forms, including awareness.

An example of a possible research initiative is microstudies on context native IT. Microstudies is an equivalent of microcredits in the domain of education. Microstudies enable a bottom-up study process where each study—performed using a mobile device—gives a narrow competence in a user-requested area. The acquired competences are stored as a digital portfolio. When a student has reached a critical set of studies, she can apply for a certificate.

The rationale of microstudies is in the massive and fast-changing educational landscape of a developing context. Educational demands are hard to forecast, mobile technology is available, and people need fast track for IT competences required at jobs. At the same time, the culture recognizes traditional, formal aspects of education, like certificates.

The exemplified research project will be carried out following the strength-based design in a given context. Representation of the learning process is a digital, interactive, multimedia-based learning story, shared by social mobile media. A focus group representing potential users identifies indicators for the functionality and relevance of microstudies.

We can summarize the challenge of context native technology with the alternative concepts of garage computing, bottom-of-the-pyramid computing or life computing. The research toward context native technology takes place in developing technology pockets, that is, a periphery far way from centers of conventional technology.

6.5 Summary

The era of fast global development sets an attractive stage for IT to return to its passionate and radical roots. Developing context native technologies will require young talents that the developing contexts are full of. The emphasis is on designing fascinating solutions that only later might find their satisfied customers. The carrying force of the challenge is the belief that fresh ideas grow in peripheries.

Acknowledgments

In addition to the review of the key academic and industry literature, this chapter reflects the lessons learned by the author during his 2 years' work as the Chief Technical Advisor in STIFIMO, a program of cooperation in Science, Technology, and Innovation between Finland and Mozambique in 2010–2014. The job offered a unique opportunity to discuss issues related to IT and global development with diverse stakeholders and also with people who did not have a clue of how science, technology, or innovation could benefit individual Mozambicans—mostly, the latter were expatriates. The opinions do not necessarily reflect those of the Ministry of Science and Technology of Mozambique or of the Finnish Ministry for Foreign Affairs. For the research part of the work, the author is indebted to the partial support from the Academy of Finland.

Using ICT for Development, Societal Transformation, and Beyond: Closing the Digital Divide in Developing Countries: Case of Egypt*

Sherif Kamel
The American University in Cairo

7.1 Overview

Developing countries around the world face various challenges across different sectors. These challenges vary depending on infrastructure availability, level of education, and economic conditions among other reasons. During the past few decades, new challenges have been imposed on the developing world. These challenges were introduced following the massive introduction and diffusion of information and communications technology (ICT) with different societies experiencing digital inclusion in some sectors but also digital exclusion and gaps in many more areas. The digital divide

* This is an updated and an amended version of "Information and Communication Technology for Development: Building the Knowledge Society in Egypt," published in *Access to Knowledge in Egypt New Research on Intellectual Property, Innovation and Development,* edited by Nagla Rizk and Lea Shaver, London, U.K.: Bloomsbury Academic, 2010, ISBN 978-1-84966-008-2, pp. 174–204.

has been described and defined in a variety of ways; it is fundamentally the gap between those who have access to and control of technology and those who do not (Tinio, 2003). In other words, the term describes the difference between the haves and the have-nots when it comes to information access and knowledge dissemination (Loch et al., 2003).

One of the important factors in bridging the digital divide is the availability of ICT and Internet skills and capacities coupled with the spread of the ICT infrastructure investment (Opesade, 2011). Unless that is realized, ICT could be the platform through which gaps widen between societies not only inter (between) but also intra (within) communities and countries alienating remote and underprivileged communities and leading to the widening of the socioeconomic gap resulting from minimal information access and dissemination as well as knowledge acquisition opportunities.

Different countries experience different reasons for which readiness of infrastructure for digital inclusion is realized. For example, in the case of South Africa, technology infrastructure and human skills exist; however, there is a need for more determination and political will from the government (Parker, 2011). Information-poor and information-rich societies are still present in different countries around the world reflecting the case of intrasociety digital divides. In the case of Egypt, closing the divide is handled by a public–private partnership where the government enabled the regulatory environment, the private sector made the bulk of the investment and the civil society had an invaluable role to play in education and learning. The diffusion of ICT is not following the conventional wisdom in most developing nations where technology is only diffused in the capital, but it is also in the remote areas, villages, and towns as well as in different cities around Egypt. According to Opesade (2011), “investment in ICT alone cannot bridge the digital divide, but a value-based investment targeted at specific developmental issues will go a long way in achieving this.” It needs a holistic view for comprehensive societal development.

While the World Bank classifies nations based on gross national income (GNI) per capita, in the ICT age, introduction, diffusion and access to information and knowledge, technology platforms, and the percentage of digital literacy are important factors for societal development and growth. Moreover, these elements are used to rank nations and represent important factors attracting companies and foreign direct investment (FDI). Penetration rates of ICT, Internet, and mobility are vital indicators that help minimizing the digital gap (Kamel and Hussein, 2002). Basic needs, food, shelter, and housing, are no more the same; both information and technology have become of primary importance. According to the World Bank (2002), “the knowledge gap in many developing countries is a contributory factor to poverty, and there is no better way to bridge this divide than through the use of ICTs.” For emerging economies and developing nations, one of the primary important issues that need to be addressed is a clearly defined information technology policy that is critical to the development of a comprehensive information technology infrastructure (Aqili and Moghaddam, 2008). These ideas were raised throughout the past decade and highlighted during the World Summit of the Information Society (WSIS) both in Geneva in 2003 and Tunis in 2005 (World Summit on the Information Society, 2008). One of the challenges that were discussed at both summits was to avail the ecosystem required to provide “a society where everyone can access and share information and knowledge that can enable individuals and communities to achieve their full potential in promoting their development and improving their quality of life, and by that the digital divide can only be closed through a collective multidimensional and multisectoral approach” (Rao, 2005). The ICT policies should be framed in conjunction with a more holistic ecosystem that serves ICT in the wider-national scale. This includes investment in education, ICT infrastructure, creating an environment conducive to ICT development and growth, and fostering innovation and entrepreneurial start-ups (Quibria et al., 2003).

The digital divide comes in different forms within countries as well as between countries. Wealthy people have better access than poor people, younger people usually have better access than older people and men usually have more access than women and usually access is better in cities rather than in rural areas (Busch, 2010). There is also a relation to the issue of classes across the community that leads to a

social hierarchy and having unequal access to resources (Lindquist, 2002). According to Illich (1973), "a convivial society would be the result of social arrangements that guarantee for each member the most ample and free access to the ICT tools of the community and limit this freedom only in favor of another member's equal freedom." Information, in itself, is a resource of immense social and economic value, and it is important as an invaluable tool for a productive, effective, and efficient economy since information impact different sectors and help rationalize the decision-making process when they are timely and accurate (Cawkell, 2001).

7.2 Introduction

Since ancient history, Egypt has witnessed massive information flows through different means. This included inscription on Rosetta stones and papyrus papers and the establishment of the library of Alexandrina, the world's first and most famous library and the gateway for knowledge creation and accessibility (Kamel, 1998a). During the middle ages, Arabic manuscripts became one of the most common means for information and knowledge dissemination. In the modern age, paper printing and publishing started in Egypt during the nineteenth century, witnessing the publishing of the first journal in Egypt in 1826. A few years later in 1830, Egypt witnessed the establishment of the first national archive system (Kamel, 1998b).

However, in the twentieth century prior to 1985, a number of characteristics identified the status of information in Egypt. The country was rich in data but poor in information, known for accumulated bureaucracy through red tape, computers were viewed as ends and not means, and there were islands of innovation with no bridges (Kamel, 1998b, 1999). From a government perspective, the focus was more on technical issues and not decision outcomes; there was poor multisector coordination and no synergy between information and socioeconomic development strategies.

Given this reality, even as ICT was increasingly becoming a necessity for socioeconomic development (Press, 1999), the government of Egypt recognized the need to take proactive measures and build the required information infrastructure. The strategy deployed followed a two-tier approach, inviting society with its different stakeholders to contribute in shaping the infostructure, which, in turn, would effectively contribute to the socioeconomic development (World Bank, 2006). Between 1985 and 2007, the government announced nine major policy initiatives to promote the development of Egypt's information society (Kamel, 2007). The policy initiatives were amongst the early attempts to close the nationwide digital divide in Egypt that was not just caused by the lack of ICT penetration rates but also by the level of illiteracy rates among the population. Such efforts were followed by a tenth policy initiative introduced in 2011 post Egypt's uprising, where ICT and universal Internet access across the nation had an invaluably effective impact in its successful realization to meet its initial targeted objective of the population as shown in Table 7.1. The tenth initiative was mainly targeting availing better and universal broadband across Egypt's different provinces. Since the uprising the Internet access grew to reach 32.4% of the population, mobility reached 105%, and Facebook 13.2% (Egypt ICT Indicators, 2012).

Since the early 1990s, Egypt has been undergoing a liberalization program of its public sector. The government has announced that it would invest in its human capital, encourage foreign direct investment (FDI), and emphasize innovative ICT as a platform for business and socioeconomic development (Kamel, 2005a). The government in collaboration with the private sector through a variety of public–private sector partnerships has announced the restructuring of sectors such as education and health as well as working on closing the digital divides and promoting social inclusion using ICT tools and applications. Egypt's population is growing at 1.9% annually with over 58% under the age of 25 years. Since 2011, over 20 million of the population have successfully capitalized on the effective use and spread of ICT through social networking and managed to voice their opinion and introduce initial changes to the political scene in Egypt. The digital inclusion of many had effective and concrete outcomes on

TABLE 7.1 ICT-Related Policy Initiatives and Programs

Year	Policy Initiatives/Programs

2007	Egypt ICT Strategy 2007–2010
2011	Broadband Initiative

engaging large segments in the community in the socioeconomic and political debates taking place in Egypt (Ghonim, 2012). Further examples include the huge increase of bloggers and online debates post January 2011, leading to being one of the top countries in the world in terms of active bloggers per capita. With the growing penetration rates in ICT-related tools and mobility, the digital divide is gradually closing across the nation, and many are gradually being digitally and socially included in the cyberspace. Many called it the emergence of Egypt 2.0.

This chapter examines the introduction and diffusion of ICT on Egyptian society and the role it played in providing awareness and access to knowledge to different clusters in the community. In January 2011, ICT applications—mainly social networks—proved to have had a direct impact on society at large being a platform enabler for Egypt's uprising that was spearheaded by the nation's youth and that successfully mobilized a nation and led to major transformation in the political landscape in Egypt. The chapter addresses four main research questions. These include: whether and how did ICT become a vehicle for development and a platform to access knowledge and minimize the digital divide? How did ICT for development policy and strategy formulation and infrastructure deployment evolve? What were the challenges and the lessons learnt from efforts aimed at using ICT for socioeconomic development? What are the implications of diffusing ICT on access to knowledge in the society in Egypt?

7.3 Building Egypt's Information Society

The idea of ICT4Development (ICT4D) came into vogue in the early 1980s when Egypt was faced with the chronic challenges of developing nations, such as debt, economic reform, public sector reform, a balance of payment deficit, a high illiteracy rate, poor technological and telecommunications infrastructure, constrained financial resources, unemployment, environmental protection, and cultural heritage preservation. During that period, Egypt was striving to implement a nationwide strategy toward its socioeconomic development objectives and ICT was identified as a catalyst for that process. Therefore, the government of Egypt adopted a set of information-based projects leading to the establishment in 1985 of the Information Project Cabinet of Egypt (IPCOM), a project that was formulated to help introduce ICT into government and public administration in Egypt. With the growing interest in what IPCOM can offer to the government and decision makers, it was transformed into the Information and Decision Support Center (IDSC), a think tank affiliated with the cabinet of Egypt. The IDSC's objective was to develop and implement, using a supply-push strategy, large informatics projects to achieve socioeconomic development using state-of-the-art ICT (El-Sherif and El-Sawy, 1988).

During the 1990s, technological innovation and economic and social organization became more tightly linked than ever. This was spreading across the government institutions, the public and private sectors as well as the civil society. Continuous innovation in ICTs geared industry and society toward

information acquisition and knowledge dissemination (Branscomb, 1994). Consequently, innovation has transformed the activities and relationships of individuals and organizations into a new information society, or *knowledge society*, in which ICT services pose both challenges and opportunities (Shapiro and Varian, 1999). The knowledge society refers to a second-generation information society. Whereas an information society aims to make information available and invent the technology necessary for this, a knowledge society aims to generate knowledge, create a culture of sharing and develop applications that operate via emerging ICTs like the Internet (ESCWA, 2005).

The knowledge society is now a force for fundamental global change (Garito, 1996). Knowledge and ICT innovation are becoming important values for business, socioeconomic development, and wealth creation with implications at the macro and micro levels (ESCWA, 2005). The changeover is complex, requiring new forms of partnership and cooperation between public and private sector organizations (Kamel and Wahba, 2002). Such partnerships were intended to engage different constituencies in the society to help leverage the role and impact of key sectors in the economy including education. This is best achieved through collaborative strategies that diffuse best practices and develop ICT applications, with the primary objectives of promoting growth and strengthening competitiveness. For many emerging economies such as Egypt, formulating strategies and policy frameworks to support the growing knowledge society could significantly accelerate development. In the context of Egypt, the goal of joining the knowledge society is to fill societal needs, create wealth, and sustainably enhance the quality of life of the community (Kamel, 2009). With a young and fresh population, the potential of a knowledgeable society will set the pace for years to come. For Egypt, intellectual power and contribution will be a crucial determining factor in the development process of the nation.

For millennia, the basic needs of humankind have been food, clothing, and shelter. Now it is time to add information to this list. Information and knowledge are nowadays the drivers in the global society, much more than land, capital, or labor. The capacity to manage knowledge-based intellect is the critical skill of this era; a firm and/or a society with a strong base of knowledge can leverage that base to create further knowledge, increasing its advantage over its competitors (Kamel and Wahba, 2002). ICT innovations are making a growing impact on business and socioeconomic development by introducing and diffusing the concepts of knowledge sharing, community development, and equality. These impacts are felt at the individual, organizational, and societal levels. ICT is not an end in itself, however, but a means of reaching broader policy objectives. The main objective of ICTs should be to improve the everyday lives of community members, fight poverty, and advance the Millennium Development Goals (MDGs). This is to a great extent related to addressing the different aspects that can help closing the digital divide. In this respect, ICT is delivering the key productivity gains that enable lives of material comfort for many around the world that would have been unthinkable only two centuries ago. Expanding access to knowledge through these new channels and tools creates emerging opportunities for learning and employment with strong implications for social and economic development. Moreover, in a country like Egypt, its young and growing human resources represents for the country “the oil of the 21st century,” an invaluable resource that could transform the nation with a strong economy and an educated society that includes over 16 million children in schools, 1.2 million students, and around 300,000 university graduates every year (Kamel, 2010).

The technology innovations could have remarkably positive implications for developing nations, if they are properly introduced and managed. However, if they are not well supported, or if ICT is marginalized in the development process, inequities may increase between the developed and developing world, leading to widening the digital divide. It is a commonplace in development literature that the developing world lacks access to ICT, leading to such a divide. Nevertheless, it is important to note that such a divide exists *within* nations, both developed and developing as well. This internal digital divide, also referred to as a gap between “haves” and “have-nots,” relates the possession of ICT resources by individuals, schools, and libraries to variables such as income level, age, ethnicity, education, gender, and rural–urban residence (Kamel, 2005b). It also addresses the illiteracy in computing as opposed to the conventional definition of illiteracy that addresses reading and writing.

The usual causes of this divide include, but are not limited to, expensive personal computers that are unaffordable for most developing country citizens, poor or limited telecommunications infrastructure especially in remote locations, and high illiteracy rates and poor educational systems (Kamel and Tooma, 2005). However, the major obstacle is the ICT ecosystem, including the complexity of the necessary operational details that need cultural adaptation and localization; this included the use of the Arabic language in what is widely known as *Arabization*. For societies to develop, grow, and benefit from the ICT revolution, nationwide introduction, adoption, diffusion, and adaptation of ICT should occur. ICT utilization is a living proof of the generation gap between different users and the case of Egypt's uprising is one of the most recent examples. However, this is rarely seen in developing nations where most of the ICT implementations and infrastructure are focused in capitals and major cities and are mainly related to conventional utilization of ICT. Universal access is becoming widely advocated where ICT should reach all the remote and underprivileged communities. This could lead to leverage educational, cultural, and societal capacities. The power and outreach of ICT could help emerging economies like Egypt leapfrog in their quest for development and growth.

The knowledge society promises to capitalize on emerging ICTs to create economic and social benefits. It encompasses ways in which various high-technology businesses, including ICT, universities, and research institutions can contribute to the economy of a nation while enabling economic sectors to operate more efficiently and effectively. In this context, Egypt has made efforts toward adapting to the changing global and technological conditions while catering to local markets. The ongoing restructuring of the ICT sector to serve development is liberalizing the telecommunications sector and opening the market to new competition. This restructuring has involved designing laws and regulations related to telecommunications, electronic commerce, intellectual copyrights and industry development; investing in human resources and promoting innovation and research and development; and promoting entrepreneurial initiatives in the marketspace in a world increasingly becoming positively affected from the removal of time and distance barriers.

It is important to note that, ICT is not the only enabler of the knowledge society. The European Commission (2003) defined the knowledge society as characterized by a number of interrelated trends, including major advances in diffusing and using ICTs, increased emphasis on innovation in the corporate and national context, the development of knowledge-intensive business service economies and knowledge management, in addition to trends toward globalization and economic restructuring. The most highly valued and profitable assets in a knowledge society are intellectual: knowledge and expertise acquired by workers. Culture is one of the most important factors in formulating the knowledge society: universities, education and training institutions from both the public and the private sectors will also need to cooperate to realize the knowledge society paradigm. This should be coupled with massive efforts to introduce and diffuse the notion of ICT and lifelong learning as a medium for leapfrogging and realizing multiplier effects on the community.

As the impact of the availability of information on socioeconomic development became apparent, governments around the globe started to invest in national information infrastructure (Petrazzini and Harindranath, 1996). Egypt, too, has heavily invested in its technology and infostructure to become the platform for the economy's development and growth (Kamel, 2005a). During the period 1985–1995, a government–private sector partnership had a remarkable impact on the build-up of Egypt's infostructure (Kamel, 1995, 1997). Hundreds of informatics projects and centers were established in different government, public, and private sector organizations targeting socioeconomic development (Kamel, 1998b). These projects included human, technological, and financial infrastructure development. They also included projects promoting entrepreneurship and transforming youth-led ideas into start-ups. Such elements represented the major building blocks necessary to establish a full-fledged infostructure capable of keeping pace with the developments taking place globally (American Chamber of Commerce in Egypt, 2001).

In 1999, ICT was identified as a priority at the highest policy level and a new cabinet office was established, namely, the Ministry of Communications and Information Technology (MCIT) (Kamel, 2005b).

MCIT was charged with the task of creating an information society, which started with the preparation of the national ICT plan. MCIT has articulated a strong vision and strategy on development and infrastructure deployment since its first national plan in 1999. The emphasis was on supporting the private sector so that it can take a leading role in transforming an ICT sector where the government could play the role of the enabler of a platform that could have various positive implications on different sectors and industries. Due to changes in global and local markets, both vision and strategy were amended in 2000 and 2004 (Kamel, 2009). MCIT took concrete steps like establishing the National Telecommunications Authority (NTRA) in 2003 and the IT Industry Development Agency (ITIDA) in 2004, and radically modernizing Egypt National Postal Organization (ENPO) in 2002. The partnership between these institutions and the ICT private sector accelerated ICT growth during the period 2006–2008, which reached 20% in 2006 and surpassed 25% in 2007 (American Chamber of Commerce in Egypt, 2007). The ICT sector is driving the gross domestic product (GDP) growth in many nations, and Egypt is no exception according to Tarek Kamel, Egypt's Minister of ICT in 2011, "we are positively contributing to the treasury through a steady growth in our services to the local community and through outsourcing." This is expected to grow given a more extensive liberalization of the sector and increasing competition with an emerging roster of local and private ICT companies in Egypt. Moreover, in 1993, the government established the Information Technology Institute (ITI) focused on providing high-end IT training for government and public and private sector employees. Almost, two decades later, ITI graduates represent the backbone and the invaluable workforce of the IT workforce in Egypt with hundreds of young promising human resource capacities trained every year. This has been the plan since the inception of ITI where the objective was to close the gap between the needs of the market in Egypt and the qualifications of Egyptian university graduates. Another divide is created by the quality of education when compared to the skills and capacities expected by different employers. "The mission of ITI is to create, shape, nurture and empower the Egyptian IT community by developing and disseminating state-of-the-art training processes," according to the minister of ICT, Mohamed Salem (Press, 2010).

The government of Egypt has formulated various initiatives to promote ICTs and pave the way for an electronically ready community that can benefit from public, universal access to knowledge. Other factors, however, will also be critical to closing the digital divide and promoting social inclusion within the digital economy: the legal and regulatory environment, awareness and capacity development, and mechanisms needed for collaboration between different sectors in the economy. The experiences vary based on the access and sophistication of the use of computers and information technology in general (Selwyn, 2006). This underscores the importance of developing national ICT strategies that recognize the role of ICT in enabling access to knowledge. In the final analysis, the challenge is to leverage ICT as a platform for knowledge dissemination in the community, and the focus should always be on outcome assessment for this strategy. The use of computers as a gateway to knowledge accessibility plays an invaluable role in such setting.

7.4 ICT4Development: How to Close the Digital Divide: Cases from Egypt

The evolution in the knowledge society heralds a new socioeconomic order. This era is witnessing the emergence of knowledge-based economies, with traditional economic, industrial, and business activities moving toward more knowledge-driven processes and the progressive transformation of advanced economies into knowledge-based, technology-driven, services-dominated economies. These shifts are increasingly laying emphasis on economic activities with intellectual content and knowledge, enabled by the development and exploitation of new information and communications technologies within all spheres of human endeavor. In the marketspace, ICT represents a massive opportunity for small- and medium-sized enterprises (SMEs), where the differential between large corporations and small

companies is relatively small. ICT can provide various opportunities for small entrepreneurs with ideas that can have impacts on employment opportunities but also develop solutions that could benefit the community.

Against that background, Egypt's government has announced efforts aiming at developing its information and knowledge base through investments in ICT and human capacity development, improving and broadening universal access to higher and quality education, and training with an emphasis on lifelong learning and creating digital content accessible to the society. Efforts in Egypt for ICT development are government-led in collaboration with the private sector and civil society. In that respect, Egypt has developed a number of policies and strategies to facilitate socioeconomic development and accelerate the transformation of the nation's economy and society to become information-rich and knowledge-based.

In May 2007, MCIT released its 2007–2010 national ICT strategy (MCIT, 2007b). The plan paved the way for the Egyptian Information Society Initiative (EISI), which represented the vision of the ICT strategy translated into specific initiatives and programs to diffuse ICT connectivity (MCIT, 2005a,b). EISI is structured around seven major tracks, each designed to help bridge the digital divide and progress Egypt's evolution into an information society (MCIT, 2005b). The theme of the strategy is "closing the digital divide and promoting social inclusion" (Table 7.2).

TABLE 7.2 Seven Tracks of the Egyptian Information Society Strategy

eReadiness "*Equal Access for All*" • Enabling all citizens with easy and affordable access to new technologies • Developing a crucial robust communication infrastructure	**eLearning** "*Nurturing Human Capital*" • Promoting the use of ICT in education • Shaping a new generation of citizens who understand ICT and are comfortable with its use in their daily lives
eGovernment "*Government Now Delivers*" • Delivering high-quality government services to the public in the format that suits them • Reaching a higher level of convenience in government services • Offering citizens the opportunity to share in the decision-making process	**eBusiness** "*A New Way of Doing Business*" • Creating new technology-based firms • Improving workforce skills • Using electronic documents • Developing ePayment infrastructure • Using ICT as a catalyst to increase employment, create new jobs, and improve competitiveness
eHealth[a] "*Increasing Health Services Availability*" • Improving citizens' quality of life and healthcare workers' work environment • Using ICT through to reach remote populations • Providing continuous training for doctors • Developing the tools for building a national health network	**eCulture** "*Promoting Egyptian Culture*" • Documenting Egyptian cultural identity by using ICT tools to preserve manuscripts and archives and index materials • Offering worldwide access to cultural and historical materials • Generating and promoting interest in Egyptian cultural life and heritage
ICT export initiative "*Industry Development*" • Fostering the creation of an export-oriented ICT industry • Developing an ICT industry that will be a powerful engine for export growth and job creation	

[a] eHealth through its growing digital infrastructure attempts to provide an information/knowledge repository that caters to patients scattered throughout Egypt's 27 provinces and who are geographically dispersed. The initiative's primary objective is to decrease the health gaps for Egyptians in remote locations and villages when compared to others who live in the capital and major cities. Empowering marginalized citizens with information access on different health issues would have long-term positive effects on the economy at large and also on closing the digital divide enabling a healthier population and a society more equipped to develop and grow (Gilbert et al., 2007).

Following is an evaluation of some of the initiatives and programs implemented by the government to capitalize on emerging ICT and disseminate knowledge to the society with all its segments, sectors, and communities. Rather than attempt to cover all seven elements of the EISI, the discussion will emphasize efforts in the eReadiness, eLearning, and eCulture areas considered of greatest relevance to the access to knowledge theme.

7.4.1 Electronic Readiness: ICT for All

Electronic readiness is a complex process that harnesses social, political, economic, infrastructure, and policy issues to bridge the digital divide. Most countries adopt the same path where an assessment of eReadiness is followed by a strategy and an action plan. Therefore, digital inclusion and equality are becoming integral factors in the electronic readiness of different societies (Kamel, 2007). Therefore, the government of Egypt announced that it was launching efforts aiming at universal, easy, affordable, and fast access to ICT for all citizens while raising awareness of the potential in ICT tools and techniques. The MCIT has implemented different programs promoting computer literacy and encouraging the use of ICT across the nation. One of these programs is "ICT for all," also known as the electronic readiness (eReadiness) building block of EISI. Recognizing universal access to ICT as key to socioeconomic development, the program is devised with two main objectives. First, it aims to assist the government policy to integrate ICT in government and public services by (a) increasing ICT penetration; (b) fostering inclusion in the knowledge society and better public services and quality of life; and (c) expanding the use of post offices to provide public services. Second and more obviously, this strategy aims to facilitate ICT access for all citizens by (a) increasing PC penetration, (b) expanding the reach of Internet connectivity and broadband to all communities, (c) raising youth employability through ICT training and (d) encouraging government employees to attain international accreditation in ICT skills. The process of ICT for all is obviously perceived to have multiple positive implications on the community including job creation and community engagement. Following is a description of three selected projects aimed at promoting electronic readiness: the Free Internet Initiative, Egypt PC 2010, and IT clubs. All three employ an implementation model of public–private partnerships in which the government's role is to articulate policy and regulatory frameworks for the private sector and civil society to implement. At the close of this section, the impact of these projects will be examined through the lens of representative indicators and secondary analyses, to assess the nation's progress in achieving its eReadiness goals.

7.4.1.1 Free Internet Initiative (Internet and Broadband Connectivity)

The Internet was first introduced to Egypt in 1993 by the Egyptian Universities Network of the Supreme Council of Egyptian Universities, originally serving 2000 users (Kamel and Hussein, 2002). In 1994, in an effort to diffuse Internet usage among the broader society, the Cabinet of Egypt's Information and Decision Support Center (IDSC) in collaboration with the Regional Information Technology and Software Engineering Center (RITSEC) began providing free Internet access on a trial basis to public and private organizations. The vertical and horizontal penetration of Internet was intending to minimize the digital gap from the outset. This was done with financial support from the government, in an attempt to boost global exposure of the local market and pave the way for commercialization of Internet services.

The free access formula was credited with accelerating the growth of Internet users, particularly within small and medium-sized enterprises and industry professionals (Kamel, 1998b). In 1996, the government replaced its free access policy with an open access policy: commercial Internet services were privatized, and a dozen Internet service providers (ISPs) began operation (Mintz, 1998). By December 2001, more than 600,000 Egyptians were online, but only 77,000 were paid subscribers, served by 51 private ISPs. Such limited growth was perceived as hindering the development of the knowledge society and creating a divide between the haves and the have-nots. Therefore, in January 2002, MCIT launched

TABLE 7.3 Electronic Readiness in Egypt

Indicators	October 1999	December 2002	December 2004	December 2006	December 2008	December 2011
Internet subscribers	300,000	1.2 million	3.6 million	6 Million	11.4 million	29.8 million
ADSL subscribers	N/A	N/A	N/A	206,150	593,042	1.65 million
Internet penetration per 100 inhabitants	0.38%	2.53%	5.57%	8.25%	15.59%	34.83%
Mobile phones	654,000	4.5 million	7.6 million	18 Million	38.06 million	78.99 million
Mobile phones penetration per 100 inhabitants	0.83%	5.76%	9.74%	23.07%	50.7%	97.93%
Fixed lines	4.9 million	7.7 million	9.5 million	10.8 million	11.4 million	8.96 million
Fixed lines penetration per 100 inhabitants	6.2%	9.8%	12.1%	13.8%	15.2%	11.98%
Public pay phones	13,300	48,000	52,700	56,449	58,002	23,664
IT clubs	30	427	1,055	1,442	1,751	2,163
ICT companies	870	1,533	1,870	2,211	2,621	4,250
IT companies	266	815	1,374	1,970	2,012	3,599
Communications companies	59	75	152	244	265	295
Services companies	88	121	148	211	242	356
IT economic indicators						
Number of employees in the ICT sector[a]	48,090	85,983	115,956	147,822	174,478	212,260

[a] There are also 26,000 indirect workers in both IT clubs and Internet cafés.

a new initiative providing free nationwide Internet access to all citizens (Kamel and Ghaffar, 2003). This has contributed to the fast-growing use, with the percentage of the population online rising from 5.5% (3.9 million users) in 2004 to 15.6% (11.4 million users) in 2008, still rising at a rate of 16.7% annually (MCIT, 2008, p. 1). Table 7.3 demonstrates the current demographics of the ICT sector in Egypt. It is important to note that huge increase in all indicators was realized post Egypt's uprising in January 2011. This was caused by an overwhelming engagement of Egypt's youth in learning, communicating, and exchanging ideas and starting-up companies as part of what has been widely known since the uprising as Egypt 2.0 and the creation of an environment that promotes freedom of expression, the private sector, and more engagement of different constituencies in the society.

Egypt's free Internet initiative has made connectivity affordable to most citizens by enabling access on all fixed phone lines without additional monthly fees. The cost of dial-up access is the same as a local telephone call, less than 5 U.S. dollars per month (MCIT, 2008, p. 4). Dial-up modems, however, are generally capable of a maximum speed of only 56 kbps and occupy the telephone line. To enhance the Internet experience, broadband (ADSL) connectivity, which supplies at least 256 kbps and does not disrupt telephone use, has been offered since 2004. The continued expansion of broadband service may be expected to positively affect access to knowledge on the web due to its reliability, stability, and capacity compared to the dial-up option. In 2011, as a reaction to Egypt's uprising, a new initiative was introduced focused on diffusing broadband across the nation's 1 million km^2. This would help reach out to the remote locations spread across the country and could be effective in one of the priority sectors in Egypt post January 2011: education.

Today, however, the higher cost of broadband connectivity still remains a challenge to its acquisition by more households. The broadband tariff initiated in 2004 has been revisited twice and in March 2009 was reduced again to 17 US dollars per month for a 256 kb speed. This cost may be further reduced by

sharing a connection across multiple households. More than 1.6 million Egyptians now subscribe to the web through broadband service, yet this is small compared with more than 29 million total Internet subscribers; this encouraged the formulation of the broadband initiative in 2011. Both figures likely reflect the use of superior connections in Internet cafés, as well as sharing of a single broadband subscription across households (MCIT, 2008, p. 4). According to a survey by Arab Advisors Group released in April 2008, 63.4% of households in Egypt with ADSL subscription reported sharing the ADSL with neighbors, and 81.9% of those share it with more than three neighboring households (Arab Advisors Group, 2008).

7.4.1.2 Computer in Every Home: Egypt PC 2010

Egypt PC 2010 is an initiative to bring Egypt as a nation online. It is an amended version of the 2002 PC for every home initiative launched in collaboration with Telecom Egypt (TE) (MCIT, 2007a). The first initiative offered locally assembled PCs with bank credit for up to 3 years, using ownership of a landline telephone as loan collateral. PCs could be bought on hire–purchase terms by anyone with a TE telephone line, with the periodic loan repayments included in the phone bill. In the original initiative, a limited variety of PC models and specifications were offered, which rendered the product unaffordable to many. Additionally, only TE customers could participate, which limited the project's scope to urban communities. These two issues hindered the success of the program among the community. Five years after the launch of the 2002 initiative, the Internet penetration rate had increased to only 7% (MCIT, 2007a). Since, as noted earlier, dial-up service is available to any home with a telephone landline at no additional charge, the slow Internet penetration rate must be attributed to the continuing difficulties to acquire home computers.

The PC 2010 initiative implemented several lessons learned. The new program offers local and international brand PCs, from simple models for beginners to high-end desktops and laptops. Participants no longer need to be TE customers to be eligible for the extended payment terms because financing banks offer the required loans through facilitated retail banking procedures. Under the new scheme, the PC can be purchased on installments for as little as 8.50 U.S. dollars per month, which comes to just over 100 U.S. dollars per year. Compared with Egypt's average GDP per capita of approximately 4337 U.S. dollars per year (UNDP, 2007, p. 231), this rate is quite affordable. Moreover, the new initiative focuses on improving PC distribution in all provinces, with an emphasis on serving underprivileged communities through partnerships with civil society organizations. This is likely to change with the broadband initiative that is currently being prepared with plans to cover Egypt across its different provinces. The importance of PC 2010 could be seen in the context that access to computers reflects the extent to which technology use enables individuals to participate and be part of society versus being social excluded through the barrier of not having access to a growing network of connected communities of interest (Berman and Philips, 2001; Haddon, 2000).

7.4.1.3 Integrated Computing and Training through IT Clubs

The digital divide is often created by the remote and demographic location of some communities that prohibits the access and use of the Internet in the first place (Katz and Aspden, 1997; Katz and Rice, 2002). These are the underprivileged societies located in rural settings especially in developing nations. This has been the case in Egypt which led to the emergence of a network of IT clubs across Egypt's 27 provinces that provide citizens with access to information technology tools and applications for minimal cost, many services are for free. Their primary objective is to open the global eSociety to Egyptian youth and rural and underprivileged communities by offering an affordable site for Internet access and training. The initial vision for the program was to open 300 such IT clubs (MCIT, 2001, p. 2). The model proved highly replicable; today there are over 2163 IT clubs across the nation, a figure still growing by approximately 13.5% annually (http://www.egyptictindicators.com). This number is likely to increase

with a growing number of business plan competitions and enabling platforms for young entrepreneurs from different provinces who are eager to start their own businesses. The American University in Cairo (AUC) School of Business Entrepreneurship and Innovation Program (EIP), the American Chamber of Commerce in Egypt, Google Egypt, Sawari Venture's Flat6 initiative, and others are among a number of organizations that have been growing regularly since January 2011 with a targeted objective to support young entrepreneurs with innovative ICT ideas that could have various impacts on the community. Most of the start-up ideas are IT services and solutions. There is a massive need for training and lifelong learning for those young and potential entrepreneurs who want to make a difference for their society and for the future of Egypt. These ICT clubs are perfectly positioned to play such much needed role in disseminating knowledge in ICT-related issues and help prepare those future private sector leaders creating jobs at the local level. An example of AUC School of Business EIP efforts is helping over 3500 seniors and fresh graduates from 11 different provinces train on taking their ICT ideas to the next level and starting their own companies. The key is to create jobs throughout the nation; this could be the most effective way to close the holistic divide that includes among its implications the digital divide.

At this time, more IT clubs are connected and many of these are remote in the sense that new IT clubs that are touring the nation in the form of buses were introduced so that those living in remote and underprivileged communities also benefit from such effort. The remote and poor villages benefited the most from this project, especially those who distantly located from major cities and towns. The case of the IT clubs diffusion in remote locations reflects the notion that it is difficult to adequately account for the effective uses of ICTs without accounting for the availability of appropriate and current ICT infrastructure (Grabill, 2003).

7.4.2 Assessing the Impact of Egypt's eReadiness Initiatives

Through the efforts exerted as described previously, significant progress has been made in achieving Egypt's eReadiness goals. As a reflection of this point, Egypt ranked 76th out of 134 economies surveyed for the 2009 Networked Readiness Index (WEF, 2009, p. xvii).* Egypt also earned recognition as "an emerging outsourcing gateway in the Middle East" (WEF, 2009, p. xiii), in part due to its competitive Internet usage charges (WEF, 2009, p. 116). An alternative eReadiness index puts Egypt even higher, at 57th out of 70 nations, noting an upward momentum due to improvements in connectivity (Economist Intelligence Unit, 2008a, p. 3).†

However, it is obvious that additional work is still needed. The slow increase in fixed line density rates, in particular, has been identified as an element slowing down Egypt's eReadiness. An external source reports that "Despite the moderate growth which Egypt's fixed-line market has continued to experience, the market has failed to keep pace with the country's expanding population" (Business Monitor International, 2008). The report predicted a shrink in the sector in 2009, with more customers relying on mobile phones in place of fixed lines. A chance to move forward again was predicted,

* The World Economic Forum (WEF) and INSEAD develop the NRI. The index is based on hard data produced by organizations such as the World Bank, the International Telecommunication Union and the United Nations, and survey data generated from the Executive Opinion Survey that is annually conducted by WEF. The three components of the index include the ICT environment created by the government, the readiness of the community's key stakeholders including government, businesses and individuals and the usage of ICT amongst those stakeholders. The index ranks Egypt 60th in terms of market environment and 70th in terms of IT infrastructure; while Egypt ranks 51st in government readiness, it is still lingering at 97th rank in individual readiness.

† The Economist Intelligence Unit's eReadiness ranking is based on a set of quantitative and qualitative criteria that include connectivy and technology infrastructure, the business environment, the social and cultural environment, the legal and policy environment, the government's policy line and business adoption. The data is sourced from such institutions as the World Bank, the World Intellectual Property Organization, and the Economist's network of national experts and economists. In 2008, Egypt held an eReadiness score of 4.81 out of 10 as opposed to 4.26 in 2007 (The Economist Intelliedence Unit, 2008b).

however, only if competition enters the market. "The arrival of a new fixed-line operator sometime in the next 2 years could result in a new round of growth for the sector, particularly if the new entrant started providing fixed wireless services," according to the former minister of ICT. Given the recent developments in Egypt, this plan has been put on hold. However, it is perceived that in the coming few years, a new fixed line operator will be introduced into the market in Egypt, which will be in favor of market competition.

Taking the long view, significant progress on eReadiness has unquestionably been made. The ICT infrastructure witnessed in the past decade massive developments in international links for telephony and the Internet backbone in addition to disseminating Internet across Egypt's 27 provinces. The ultimate goal, however, is not to achieve increased ICT adoption for its own sake. As the name "eReadiness" implies, these efforts merely lay the foundation to take advantage of ICT tools for development ends. With this in mind, the following section examines Egypt's efforts to date in leveraging ICT development for education.

7.4.3 Electronic Learning: ICT for Education

Education and lifelong learning are central drivers of socioeconomic development and growth, and have particularly relevant implications for access to knowledge. Boosting performance on these measures, however, has historically been a challenge for Egypt. The country's adult literacy rate stands at only 71.4% (UNDP, 2007, p. 231), indicating that a substantial proportion of the country must overcome barriers beyond the merely technological in order to take advantage of the Internet. Egypt's education system has been fully subsidized by the government for decades, yet challenges with regard to infrastructure and quality persist. In the public school system, class sizes of 70–80 pupils are common, teachers are poorly qualified, and the emphasis is on rote memorization rather than problem-solving (Kozma, 2004, pp. 14–15). Since 2003, the country's former ruling National Democratic Party has declared education reform to be a key priority (Essam El-Din, 2003); nothing has materialized in a sector that has been suffering since the coup d'état of 1952 that always managed the education sector based on a fire fighting approach rather than developing a holistic approach that could transform a sector highly needed for socioeconomic development. This has been one of the key elements for the creation of the knowledge and digital gaps in the community. Education has been and will always be the determining platform of whether these gaps diminish or grow.

One major component of such reform is embedding ICT in education to promote information acquisition and knowledge dissemination. The objectives of deploying ICT for education include optimizing ICT investments to avail the required infrastructure that promotes education and lifelong learning, satisfying the ICT industry training requirements, creating an open learning environment by connecting the education community through broadband, and increasing the efficiency and effectiveness of education institutions and embedding ICT in the curriculum. Based on the events of January 2011, the growing access to ICT tools and applications and the exposure of Egypt's youth were benefiting from enabling the unconventional use of the technological platforms in changing the political landscape of the nation.

Toward those ends, MCIT is supposed to work closely and strategically with the Ministry of Education (MOE) and Ministry of Higher Education and Scientific Research (MOHE); where in the context of developing nations, ICT deployment is invaluable for educational improvement and spread across the society. Accordingly, a number of projects were devised; most notably the Smart Schools Network, the Egyptian Education Initiative (EEI), and ICT for Illiteracy Eradication. These programs share the common target of increasing ICT awareness and promoting education and lifelong learning. Their strategy is meant to capitalize on the potential of ICT to provide universal access to knowledge and education to all constituencies in Egypt, irrespective of socioeconomic group, gender, age, or background. Egypt offers a model for how rising economies can develop a skilled IT workforce and a healthy IT sector that are closely aligned with each other.

7.4.4 Assessing the Impact of Egypt's eLearning Initiatives

Although Egypt has made significant progress in achieving its eReadiness objectives, its eLearning programs are generally still at the pilot stage. According to a regional report, Egypt's ICT for education implementation was ranked at a maturity level of two out of four, indicating a number of sporadic projects and initiatives that had concrete impacts, but lacking the consistency and long-term vision for successful implementation and sustainability (ESCWA, 2007). It is important to note that of the three-eLearning programs, the Egyptian Education Initiative has had the greatest impact, training over 100,000 teachers in using ICT. The Smart Schools Network, although still quite small, holds the potential to build on this success to use ICT in a way that truly transforms the educational experience. Finally, the ICT for Illiteracy Eradication project demonstrates that eLearning can be leveraged to achieve results in lifelong learning, even for those at the greatest educational disadvantage. To achieve a significant impact upon access to knowledge in Egypt, however, these programs must be greatly scaled up. This will require broader advancements in access to computers and the Internet (eReadiness) than has already been achieved. Once this infrastructure is in place, however, the eLearning programs may benefit from the economics of easily reproduced open source software to scale up with an efficiency of resources.

7.5 Social Networks Impact: 2011 and Beyond

In recent years, many case studies indicated that ICT tools and applications including mobile phones, short messaging systems (SMS), and the Internet have had a variety of impacts on democratic freedoms (Shirazi et al., 2010). The provision of such tools and applications are central to information access and participation in social and political life (Becker, 2001; Bennett and Fielding, 1997; Drezner and Farrell, 2008; Harwit and Clark, 2001; Snellen, 2001). These mechanisms help facilitate the diffusion of information and in many ways help in closing the digital divide and in improving social inclusion (Norris, 1999). Moreover, some people think that ICT diffusion help create a new type of technology adopter called the "digital citizen" (Katz and Aspden, 1997). According to Balkin (2004), "the digital revolution brings features of freedom of expression to the forefront of our concern and makes possible for widespread cultural participation and interaction."

ICTs provided the platform to enable citizens the participation in the transformation and democratization process as well as mobilization of resources, debating issues, influencing decisions, and leveraging civic engagement, all contributing to minimizing the digital divide (Bennett and Fielding, 1997; Dertouzos, 1997 and Sussman, 1997; Gilbreth and Otero, 2001; Norris, 2001; Suarez, 2006; Weber et al., 2003).

The impact of ICT with an emphasis on social networking was optimized in Egypt in the past few years. This was spread across the community. It also enabled an effective platform to oppose the convention wisdom that in the Middle East women face unequal access to the Internet. Social networking phenomenal growth, from 6 to 20 million in 18 months, allowed social inclusion through the digital world for different groups including women, youth, and underprivileged communities in remote areas in Egypt. Since 2008, Egypt's youth (58% of the population totaling 90 million in March 2012) realized the power of sharing news, knowledge, and momentum using emerging ICT tools and applications, social networking. Applications such as Facebook were growing in popularity in the Middle East region for a few years now recording, as a region, one of the highest growth rates in the world. The tools were perceived as a platform to share ideas, empower them, as well as a mechanism that can help transform the society. This is made clear in Ghonim's statement, as one of the young Egyptians who contributed in Egypt's uprising "the power of the people is greater that the people in power" (Ghonim, 2012). The experience witnessed in Egypt in early 2011 for the duration of 18 days demonstrated the power ICT can provide and how access to information and knowledge in a nation that is one million square kilometers can be effective with concrete impacts. As an attempt to stop the uprising, one of the strategies used by the government of Egypt was cutting-off cellular phones and Internet connectivity; a clear statement of

how effective communication devices were influential, even in a country that rates high in illiteracy. In the case of Egypt, the Internet has been instrumental in setting the stage for a revival of Egypt's political scene for the first time in 60 years. There is no doubt that ICT and social networks made public exposure inevitable (Ghonim, 2012). In the build-up to January 2011 and to date, the impact on the growth of Internet users and mobile holders was phenomenal as indicated earlier. Mobile phones have increasingly and effectively helped in closing the digital divide among the different constituencies of the community irrespective their social class, income, educational background, skills, and capacities (James, 2011). In many ways, the likes of Facebook and Twitter in Egypt became the primary news channel of communication for many Egyptians both in Egypt and with the over 6 million Egyptians who are living around the world but very much connected to their homeland. Over a year after Egypt's uprising, the transformation process continues in different models using various ICT tools and techniques supported by several ICT-based business plan competitions and initiatives that target several start-ups aiming at addressing socioeconomic and political issues and developing solutions and suggestions to approach them by different constituencies.

7.6 Conclusion

Over the past decade, Egypt has made significant progress toward realizing the vision of the knowledge society through ICT. The developments of the initial phase addressed legal, technical, and business fundamentals, enabling the ICT industry to develop significantly (IDSC, 2005). These have been reflected positively in the overall growth of the sector, which exceeded 20% during the period 2006–2008 and contributed to overall GDP growth by more than 7% (Fayed, 2009). In the words of the former ICT minister, the ICT sector has transformed itself "from a sector looking for support and subsidies to a sector contributing tangibly and intangibly to the economy with a total of 5.2 billion US dollars received by the treasury since early 2006" (Kamel, 2008). The ICT sector has also served as a role model for other sectors of reform and liberalization, capitalizing on a free market economy and catering to different social groups and interests.

The National ICT Action Plan 1999–2009 was realized in many ways over the past decade, although not in its full capacity as envisioned in 1999. This action plan, set shortly after the establishment of MCIT, aimed to build a knowledge-based society that can boost socioeconomic development and entice economic growth. As originally conceived, the plan identified eight goals: *completing the ICT infrastructure build-up* to avail universal interconnectivity among all 27 provinces including 520 local administrations and over 8000 cities and villages; *realizing infostructure interconnectivity* among value-added information networks in government, private sector, and civil society organizations; *linking Egypt locally and globally* within the growing global digital marketspace; *investing in human capital* through lifelong learning programs and serving different segments of the community; *building an electronically ready community* capable of engaging in the global information society; *updating Egypt's information infrastructure* as a step in building the nation's information highway; *encouraging an ICT export industry* by promoting and supporting innovation, creativity, and research and development in ICT-related areas; and *collaborating through public–private partnerships* engaging different stakeholders in high-tech projects with business and socioeconomic implications.

Although none of these objectives have been fully attained, the achievements to date of the plan lie in gradually helping Egypt to bridge the nation's digital divide and in sharpening its competitive edge on the global ICT scene. Penetration rates are gradually increasing for infrastructure like Internet access, PCs, and mobile and fixed phone lines. The liberalization of the telecom sector created competitive forces that are working for the best interest of the consumer; more is expected in the years to come. The action plan also helped avail an ecosystem that is empowered by deregulation policies, which laid the foundations of the ICT sector's continuing development. The MCIT has gained valuable experience through a number of public–private partnership initiatives that can be expanded and improved upon to achieve fully the vision of the knowledge society over the coming decade.

The development of the knowledge society cannot be left to market forces; it deserves and needs the attention of the highest political decision-makers with a vision to expanding access and contribution to knowledge. Nations like Egypt should prioritize information needs for business and socioeconomic development, just as they do already for sectors such as industry, agriculture, education, and health. Governments are responsible for taking a strategic approach to the demands of an information-intensive global environment. This approach should include creating a shared vision of the knowledge society, intensifying the process of information acculturation, generating the necessary human capacities, accelerating the development and deployment of ICT infrastructure, and building an electronically ready community.

A critical issue in the information age will be developing a win–win partnership between the government and the private sector. According to the former MCIT Minister Tarek Kamel, "institutional build up is important for the optimization of effective impacts of ICT on the society" Transparency is important. Adherence to law is important. But I believe that the most crucial issue is genuine public–private partnership including all the various stakeholders in the dialogue and in the development process (Atallah, 2008). The private sector is now seen as a major stakeholder in the progress toward the knowledge society. Use of public–private partnerships will continue to be instrumental for the government's strategy. The nature of this partnership will be determined by the answer to this question: how will governance be exercised in the information-based world? While the framework is not yet defined, the private sector will probably provide information-based services while governments construct a supporting regulatory framework based on the greater public participation and consensus essential for a knowledge society.

The knowledge society requires not just an intricate web of legal measures but also a strong, comprehensive infrastructure, a human resource investment plan, good education, and concrete incentives for local and foreign investments. Moreover, it requires full transparency in the transfer and use of data within an environment that encourages creativity and innovation. Information is power, and it is a factor in the manipulation of discourse about socioeconomic reform (Stiglitz, 2002). Historically in Egypt, the government has dominated the supply of information. The process of information sharing and dissemination was orchestrated by a number of public and private sector organizations led by the Central Agency for Public Mobilization and Statistics (CAPMAS), established in 1964 and considered the official source of data collection in the nation (El-Mikawy and Ghoneim, 2005). This strategy has been gradually changing since the mid-1980s, when the government opted for a relatively more transparent strategy by collaborating with the private sector and by allowing research entities to conduct market studies, sharing findings and outcomes, and generally contributing in the build-up of the knowledge society. This promising trend has opened venues for information sharing to the public, empowered the society, and disclosed opportunities for business and socioeconomic development.

Access to knowledge will not reach all segments of the society across all provinces, however, until further efforts are expended. Despite significantly increasing ICT penetration rates, too many Egyptians are still excluded from the opportunity to participate in the knowledge society. Not only technological expansion is needed, but also educational opportunities and the economic resources for Egypt's people to avail themselves of the opportunities the new technologies provide. Moreover, a political revisiting and reform for media freedom will be conducive to an improved access to information, which is currently still perturbed by a series of legal and extra-legal restrictions. A critical leveraging of the potential of open source software and open-licensed content is also in order to expand access to eLearning and eCulture. This is becoming on-the-top priorities of the agenda especially with Egypt's uprising and the growing role of ICT, the Internet, and social networking in information sharing, acquisition, and dissemination.

In this respect, access to knowledge emerges as an invaluable platform for development and growth in the global marketplace of the twenty-first century. With the increasing competition taking place around the world, investing in human capacities and disseminating knowledge through multiple channels is integral to business and socioeconomic development. Expanding access to ICT plays a pivotal role in this effort. Over the next decade, Egypt should further develop its ICT policies and programs within an

overall ecosystem that entices knowledge sharing and collaborative work, and which is guided by the notion that access to knowledge is the path to societal development and growth.

The developing world must understand the importance of ICT in order to optimize the associated benefits. ICT investments and infrastructure should be considered as a platform, a tool for development; only then ICT can help solve societal problems and realize its targeted objectives. ICT, through connectivity, timeliness, currency, and accessibility, is an enabling environment for digital inclusion and can have positive and concrete impacts on different sectors such as education, health, and more. Bridging the digital divide goes beyond the influence of ICT penetration. Closing the gap caused by the digital divide is a precondition to many more influences on the community including reducing poverty, improving economic conditions, supporting education diffusion, and achieving sustainable markets. While the digital divide reflects the gap in information and knowledge access, it also relates to gaps that relate to different elements including economic, social, political, and cultural aspects. In addition, it is important to note the role of income and education as significant contributors to access to computers and the Internet (Grabill, 2003). Access to information and the closing of the digital divide within the community is becoming as important as the creation of wealth, jobs, and prosperity for citizens.

Technical Foundations of Data and Database Management

8 Data Models

Avi Silberschatz
Yale University

Henry F. Korth
Lehigh University

S. Sudarshan
Indian Institute of Technology Bombay

Underlying the structure of a database is the concept of a *data model*. Modeling is done at three levels of abstraction: physical, logical, and view. The physical level describes how data are stored at a low level and captures implementation details that are not covered in this chapter. The logical level describes the real-world entities to be modeled in the database and the relationships among these entities. The view level describes only a part of the entire database and serves the needs of users who do not require access to the entire database. Typically in a database, the same data model is used at both the logical and the view levels. Data models differ in the primitives available for describing data and in the amount of semantic detail that can be expressed.

Database system interfaces used by application programs are based on the logical data model; databases hide the underlying implementation details from applications. This conceptual separation of physical organization from logical structure allows the implementation of database applications to be independent of the underlying implementation of the data structures representing the data. The low-level implementations affect system performance and there has been considerable effort to design physical organizations that take advantage of how certain applications access data and how the underlying computer architectures store and manipulate data.

In this chapter, we focus on logical data models. In Section 8.1 we cover the relational data model. In Section 8.2 we cover object-based data models including the E-R model (in Section 8.2.1), the object-oriented model (in Section 8.2.2), and the object-relational model (in Section 8.2.3). The E-R model is a representative of a class of models called semantic data models, which provide richer data structuring and modeling capabilities than the record-based format of the relational model.

In Section 8.3, we describe two models for representing nested structures, namely, XML (in Section 8.3.1) and JSON (in Section 8.3.2). These models are widely used for data exchange between applications. In Section 8.5 we outline models for streaming data.

Our coverage of data models is intended as an introduction to the area. In Section 8.6 we provide references for further reading on the topics covered in this chapter, as well as on related topics such as data modeling issues related to knowledge representation.

8.1 Relational Model

The *relational model* is today the primary data model for commercial data-processing applications. It has attained its primary position because of its simplicity, which eases the job of the programmer, as compared to earlier data models.

A relational database consists of a collection of *tables*, each of which is assigned a unique name. An *instance* of a table storing customer information is shown in Table 8.1 The table has several rows, one for each customer, and several columns, each storing some information about the customer. The values in the *customer-id* column of the *customer* table serve to uniquely identify customers, while other columns store information such as the name, street address, and city of the customer.

The information stored in a database is broken up into multiple tables, each storing a particular kind of information. For example, information about accounts and loans at a bank would be stored in separate tables. Table 8.2 shows an instance of the *loan* table, which stores information about loans taken from the bank.

In addition to information about "entities" such as customers or loans, there is also a need to store information about "relationships" between such entities. For example, the bank needs to track the relationship between customers and loans. Table 8.3 show the *borrower* table, which stores information indicating which customers have taken which loans. If several people have jointly taken a loan, the same loan number would appear several times in the table with different customer-ids (e.g., loan number L-17). Similarly, if a particular customer has taken multiple loans, there would be several rows in the table with the customer-id of that customer (e.g., 019-28-3746), with different loan numbers.

TABLE 8.1 The *Customer* Table

Customer-Id	Customer-Name	Customer-Street	Customer-City
019-28-3746	Smith	North	Rye
182-73-6091	Turner	Putnam	Stamford
192-83-7465	Johnson	Alma	Palo Alto
244-66-8800	Curry	North	Rye
321-12-3123	Jones	Main	Harrison
335-57-7991	Adams	Spring	Pittsfield
336-66-9999	Lindsay	Park	Pittsfield
677-89-9011	Hayes	Main	Harrison
963-96-3963	Williams	Nassau	Princeton

TABLE 8.2 The *Loan* Table

Loan-Number	Amount
L-11	900
L-14	1500
L-15	1500
L-16	1300
L-17	1000
L-23	2000
L-93	500

TABLE 8.3 The *Borrower* Table

Customer-Id	Loan-Number
019-28-3746	L-11
019-28-3746	L-23
244-66-8800	L-93
321-12-3123	L-17
335-57-7991	L-16
555-55-5555	L-14
677-89-9011	L-15
963-96-3963	L-17

8.1.1 Formal Basis

The power of the relational data model lies in its rigorous mathematical foundations and a simple user-level paradigm for representing data. Mathematically speaking, a *relation* is a subset of the Cartesian product of an ordered list of domains. For example, let E be the set of all employee identification numbers, D the set of all department names, and S the set of all salaries. An employment relation is a set of 3-tuples (e,d,s) where $e \in E$, $d \in D$, and $s \in S$. A tuple (e,d,s) represents the fact that employee e works in department d and earns salary s.

At the user level, a relation is represented as a table. The table has one column for each domain and one row for each tuple. Each column has a name, which serves as a column header, and is called an *attribute* of the relation. The list of attributes for a relation is called the *relation schema*. The terms table and relation are used synonymously, as are row and tuple, as also column and attribute.

Data models also permit the definition of *constraints* on the data stored in the database. For instance, *key constraints* are defined as follows. If a set of attributes L is specified to be a *super-key* for relation r, in any consistent ("legal") database, the set of attributes L would uniquely identify a tuple in r; that is, no two tuples in r can have the same values for all attributes in L. For instance, *customer-id* would form a super-key for relation *customer*. A relation can have more than one super-key, and usually one of the super-keys is chosen as a *primary key*; this key must be a minimal set, that is, dropping any attribute from the set would make it cease to be a super-key.

Another form of constraint is the *foreign key* constraint, which specifies that for each tuple in one relation, there must exist a matching tuple in another relation. For example, a foreign key constraint *from borrower referencing customer* specifies that for each tuple in *borrower*, there must be a tuple in *customer* with a matching *customer-id* value.

Users of a database system may query the data, insert new data, delete old data, or update the data in the database. Of these tasks, the task of querying the data is usually the most complicated. In the case of the relational data model, since data are stored as tables, a user may query these tables, insert new tuples, delete tuples, and update (modify) tuples. There are several languages for expressing these operations.

The tuple relational calculus and the domain relational calculus are nonprocedural languages that represent the basic power required in a relational query language. Both of these languages are based on statements written in mathematical logic. We omit details of these languages.

The relational algebra is a procedural query language that defines several operations, each of which takes one or more relations as input, and returns a relation as output. For example:

- The *selection* operation is used to get a subset of tuples from a relation, by specifying a predicate. The selection operation $\sigma_P(r)$ returns the set of tuples of r that satisfy the predicate P.
- The *projection* operation, $\Pi_L(r)$, is used to return a relation containing a specified set of attributes L of a relation r, removing the other attributes of r.
- The *union*, operation $r \cup s$ returns the union of the tuples in r and s. The *intersection* and *difference* operations are similarly defined.

- The *natural join* operation ⋈ is used to combine information from two relations. For example, the natural join of the relations *loan* and *borrower*, denoted *loan* ⋈ *borrower*, would be the relation defined as follows. First, match each tuple in *loan* with each tuple in *borrower* that has the same values for the shared attribute *loan-number*; for each pair of matching tuples, the join operation creates a tuple containing all attributes from both tuples; the join result relation is the set of all such tuples.

  For instance, the natural join of the *loan* and *borrower* tables in Tables 8.2 and 8.3 contains tuples (L-17, 1000, 321-12-3123) and (L-17, 1000, 963-96-3963), since the tuple with loan number L-17 in the *loan* table matches two different tuples with loan number L-17 in the *borrower* table.

The relational algebra has other operations as well, for instance, operations that can aggregate values from multiple tuples, for example, by summing them up, or finding their average.

Since the result of a relational algebra operation is itself a relation, it can be used in further operations. As a result, complex expressions with multiple operations can be defined in the relational algebra.

Among the reasons for the success of the relational model are its basic simplicity, representing all data using just a single notion of tables, as well as its formal foundations in mathematical logic and algebra.

The relational algebra and the relational calculi are terse, formal languages that are inappropriate for casual users of a database system. Commercial database systems have, therefore, used languages with more "syntactic sugar." Queries in these languages can be translated into queries in relational algebra.

8.1.2 SQL

The SQL language has clearly established itself as *the* standard relational database language. The SQL language has a data definition component for specifying schemas, and a data manipulation component for querying data as well as for inserting, deleting, and updating data.

We illustrate some examples of queries and updates in SQL. The following query finds the name of the customer whose customer-id is 192-83-7465:

```
select customer.customer-name
from customer
where customer.customer-id = '192-83-7465'
```

Queries may involve information from more than one table. For instance, the following query finds the amount of all loans owned by the customer with customer-id 019-28-3746:

```
select loan.loan-number, loan.amount
from borrower, loan
where borrower.customer-id = '019-28-3746' and
borrower.loan-number = loan.loan-number
```

If the previous query were run on the tables shown earlier, the system would find that the loans L-11 and L-23 are owned by customer 019-28-3746, and would print out the amounts of the two loans, namely, 900 and 2000.

The following SQL statement adds an interest of 5% to the loan amount of all loans with amount greater than 1000.

```
update loan
set amount = amount * 1.05
where amount > 10000
```

Over the years, there have been several revisions of the SQL standard. The most recent is SQL:2011.

QBE and Quel are two other significant query languages. Of these, Quel is no longer in widespread use. Although QBE itself is no longer in use, it greatly influenced the QBE-style language in Microsoft Access.

8.1.3 Relational Database Design

The process of designing a conceptual-level schema for a relational database involves the selection of a set of relation schemas. There are several approaches to relational database design. One approach, which we describe later, in Section 8.2.1, is to create a model of the enterprise using a higher-level data model, such as the entity-relationship model, and then translate the higher-level model into a relational database design.

Another approach is to directly create a design, consisting of a set of tables and a set of attributes for each table. There are often many possible choices that the database designer might make. A proper balance must be struck among three criteria for a good design:

1. Minimization of redundant data
2. Ability to represent all relevant relationships among data items
3. Ability to test efficiently data dependencies that require certain attributes to be unique identifiers

To illustrate these criteria for a good design, consider a database of employees, departments, and managers. Let us assume that a department has only one manager, but a manager may manage one or more departments. If we use a single relation *emp-info1*(*employee, department, manager*), then we must repeat the manager of a department once for each employee. Thus we have *redundant* data.

We can avoid redundancy by *decomposing* (breaking up) the above relation into two relations *emp-mgr*(*employee, manager*) and *emp-dept*(*manager, department*). However, consider a manager, Martin, who manages both the sales and the service departments. If Clark works for Martin, we cannot represent the fact that Clark works in the service department but not the sales department. Thus we cannot represent all relevant relationships among data items using the decomposed relations, such a decomposition is called a *lossy-join decomposition*. If instead, we chose the two relations *emp-dept*(*employee, department*) and *dept-mgr*(*department, manager*), we would avoid this difficulty, and at the same time avoid redundancy. With this decomposition, joining the information in the two relations would give back the information in *emp-info1*, such a decomposition is called a *lossless-join decomposition*.

There are several types of data dependencies. The most important of these are *functional dependencies*. A functional dependency is a constraint that the value of a tuple on one attribute or set of attributes determines its value on another. For example, the constraint that a department has only one manager could be stated as "department functionally determines manager." Because functional dependencies represent facts about the enterprise being modeled, it is important that the system check newly inserted data to ensure no functional dependency is violated (as in the case of a second manager being inserted for some department). Such checks ensure that the update does not make the information in the database inconsistent. The cost of this check depends on the design of the database.

There is a formal theory of relational database design that allows us to construct designs that have minimal redundancy, consistent with meeting the requirements of representing all relevant relationships, and allowing efficient testing of functional dependencies. This theory specifies certain properties that a schema must satisfy, based on functional dependencies. For example, a database design is said to be in a *Boyce–Codd normal form* if it satisfies a certain specified set of properties; there are alternative specifications, for instance, the *third normal form*. The process of ensuring that a schema design is in a desired normal form is called *normalization*.

More details can be found in standard textbooks on databases; Abiteboul et al. [AHV95] provide a detailed coverage of database design theory.

8.1.4 History

The relational model was developed in the late 1960s and early 1970s by E. F. Codd. For this work, Codd won the most prestigious award in computing, the ACM A. M. Turing Award. The 1970s saw the development of several experimental database systems based on the relational model and the emergence of a formal theory to support the design of relational databases. The commercial application of relational databases began in the late 1970s, but was limited by the poor performance of early relational systems. During the 1980s, numerous commercial relational systems with good performance became available. The relational model has since established itself as the primary data model for commercial data processing applications.

Earlier generation database systems were based on the *network data model* or the *hierarchical data model*. Those two older models are tied closely to the data structures underlying the implementation of the database. We omit details of these models since they are now of historical interest only.

8.2 Object-Based Models

The relational model is the most widely used data model at the implementation level; most databases in use around the world are relational databases. However, the relational view of data is often too detailed for conceptual modeling. Data modelers need to work at a higher level of abstraction.

Object-based logical models are used in describing data at the conceptual level. The object-based models use the concepts of *entities* or *objects* and relationships among them rather than the implementation-based concepts of the record-based models. They provide flexible structuring capabilities and allow data constraints to be specified explicitly. Several object-based models are in use; some of the more widely known ones are

- The entity-relationship model
- The object-oriented model
- The object-relational model

The entity-relationship model has gained acceptance in database design and is widely used in practice. The object-oriented model includes many of the concepts of the entity-relationship model, but represents executable code as well as data. The object-relational data model combines features of the object-oriented data model with the relational data model.

8.2.1 Entity-Relationship Model

The E-R data model represents the information in an enterprise as a set of basic objects called *entities*, and *relationships* among these objects. It facilitates database design by allowing the specification of an *enterprise schema*, which represents the overall logical structure of a database. The E-R data model is one of several *semantic data models*; that is, it attempts to represent the meaning of the data. In addition to providing an easily understood conceptual view of a database design, an E-R design can be converted algorithmically to a relational design that often requires little further modification.

8.2.1.1 Basics

There are three basic notions that the E-R data model employs: entity sets, relationship sets, and attributes. An *entity* is a "thing" or "object" in the real world that is distinguishable from all other objects. For example, each person in the universe is an entity.

Each entity is described by a collection of features, called *attributes*. For example, the attributes *account-number* and *balance* may describe one particular account in a bank, and they form attributes of the *account* entity set. Similarly, attributes *customer-name*, *customer-street* address, and *customer-city* may describe a *customer* entity.

The values for some attributes may uniquely identify an entity. For example, the attribute *customer-id* may be used to uniquely identify customers (since it may be possible to have two customers with the same name, street address, and city). A unique customer identifier must be assigned to each customer.

An entity may be concrete, such as a person or a book, or it may be abstract, such as a bank account, or a holiday, or a concept.

An *entity set* is a set of entities of the same type that share the same properties (attributes). The set of all persons working at a bank, for example, can be defined as the entity set *employee*, and the entity John Smith may be a member of the *employee* entity set. Similarly, the entity set *account* might represent the set of all accounts in a particular bank. An E-R design thus includes a collection of entity sets, each of which contains any number of entities of the same type.

Attributes are descriptive properties possessed by all members of an entity set. The designation of attributes expresses that the database stores similar information concerning each entity in an entity set; however, each entity has its own value for each attribute. Possible attributes of the *employee* entity set are *employee-name*, *employee-id*, and *employee-address*. Possible attributes of the *account* entity set are *account-number* and *account-balance*. For each attribute, there is a set of permitted values called the *domain* (or *value set*) of that attribute. The domain of the attribute *employee-name* might be the set of all text strings of a certain length. Similarly, the domain of attribute *account-number* might be the set of all positive integers.

Entities in an entity set are distinguished based on their attribute values. A set of attributes that suffices to distinguish all entities in an entity set is chosen, and called a *primary key* of the entity set. For the *employee* entity set, *employee-id* could serve as a primary key; the enterprise must ensure that no two people in the enterprise can have the same employee identifier.

A *relationship* is an association among several entities. Thus, an *employee* entity might be related by an *emp-dept* relationship to a *department* entity where that employee entity works. For example, there would be an *emp-dept* relationship between John Smith and the bank's credit department if John Smith worked in that department. Just as all *employee* entities are grouped into an *employee* entity set, all *emp-dept* relationship instances are grouped into an *emp-dept relationship set*. A relationship set may also have descriptive attributes. For example, consider a relationship set *depositor* between the *customer* and the *account* entity sets. We could associate an attribute *last-access* to specify the date of the most recent access to the account. The relationship sets *emp-dept* and *depositor* are examples of a binary relationship set, that is, one that involves two entity sets. Most of the relationship sets in a database system are binary.

The overall logical structure of a database can be expressed graphically by an *E-R diagram*. There are multiple different notations used for E-R diagrams; we describe in the following one of the widely used notations, based on the one proposed by Chen [Che76]. Such a diagram consists of the following major components:

- *Rectangles*, which represent entity sets
- *Ellipses*, which represent attributes
- *Diamonds*, which represent relationship sets
- *Lines*, which link entity sets to relationship sets, and link attributes to both entity sets and relationship sets

An entity-relationship diagram for a portion of our simple banking example is shown in Figure 8.1. The primary key attributes (if any) of an entity set are shown underlined.

Composite attributes are attributes that can be divided into subparts (that is, other attributes). For example, an attribute *name* could be structured as a composite attribute consisting of *first-name*, *middle-initial*, and *last-name*. Using composite attributes in a design schema is a good choice if a user wishes to refer to an entire attribute on some occasions, and to only a component of the attribute on other occasions.

The attributes in our examples so far all have a single value for a particular entity. For instance, the *loan-number* attribute for a specific loan entity refers to only one loan number. Such attributes are said

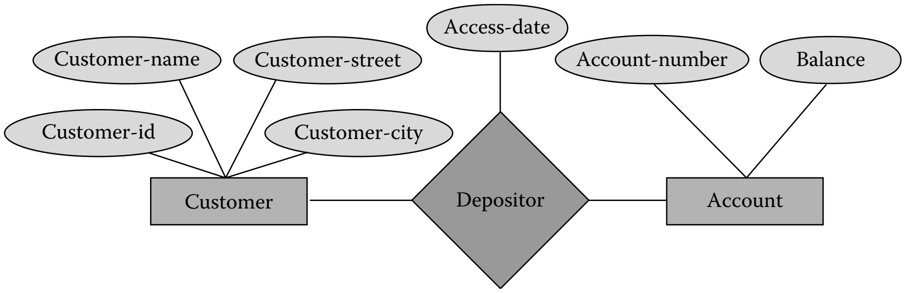

FIGURE 8.1 E-R diagram.

to be *single valued*. There may be instances where an attribute has a set of values for a specific entity. Consider an *employee* entity set with the attribute *phone-number*. An employee may have zero, one, or several phone numbers, and hence this type of attribute is said to be *multivalued*.

Suppose that the *customer* entity set has an attribute *age* that indicates the customer's age. If the *customer* entity set also has an attribute *date-of-birth*, we can calculate *age* from *date-of-birth* and the current date. Thus, *age* is a *derived attribute*. The value of a derived attribute is not stored, but is computed when required.

Figure 8.2 shows how composite, multivalued, and derived attributes can be represented in the E-R notation. Ellipses are used to represent composite attributes as well as their subparts, with lines connecting the ellipse representing the attribute to the ellipse representing its subparts. Multivalued attributes are represented using a double ellipse, while derived attributes are represented using a dashed ellipse.

Figure 8.3 shows an alternative E-R notation, based on the widely used UML class diagram notation, which allows entity sets and attributes to be represented in a more concise manner. The figure shows the *customer* entity set with the same attributes as described earlier, the *account* entity set with attributes *account-number* and *balance*, and the *depositor* relationship set with attribute *access-date*. For more details on this alternative E-R notation, see [SKS11].

Most of the relationship sets in a database system are *binary*, that is, they involve only two entity sets. Occasionally, however, relationship sets involve more than two entity sets. As an example, consider the entity sets *employee*, *branch*, and *job*. Examples of *job* entities could include manager, teller, auditor, and so on. Job entities may have the attributes *title* and *level*. The relationship set *works-on* among

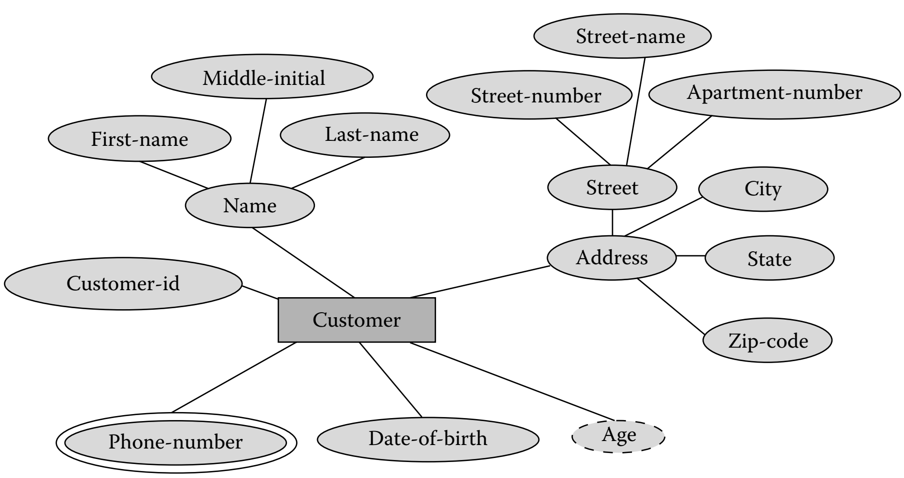

FIGURE 8.2 E-R diagram with composite, multivalued, and derived attributes.

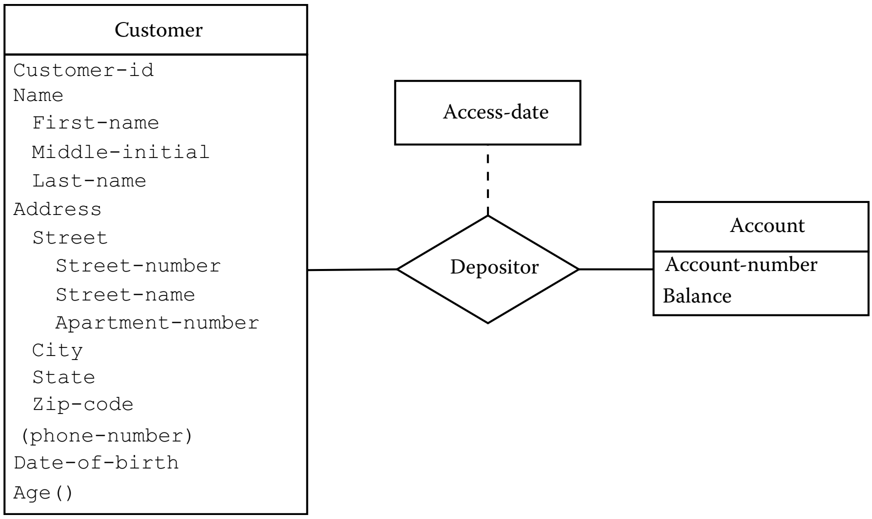

FIGURE 8.3 Alternative E-R diagram notation based on UML.

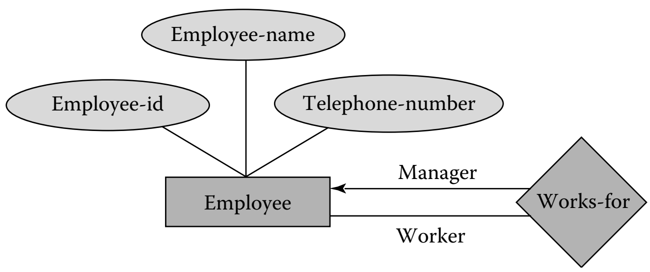

FIGURE 8.4 E-R diagram with role indicators.

employee, *branch*, and *job* is an example of a *ternary relationship*. A ternary relationship among Jones, Perryridge, and manager indicates that Jones acts as a manager at the Perryridge branch. Jones could also act as auditor at the Downtown branch, which would be represented by another relationship. Yet another relationship could be among Smith, Downtown, and teller, indicating Smith acts as a teller at the Downtown branch.

Consider, for example, a relationship set *works-for* relating the entity set *employee* with itself. Each employee entity is related to the entity representing the manager of the employee. One employee takes on the role of *worker*, whereas the second takes the role of *manager*. Roles can be depicted in E-R diagrams as shown in Figure 8.4.

Although the basic E-R concepts can model most database features, some aspects of a database may be more aptly expressed by certain extensions to the basic E-R model. Commonly used extended E-R features include specialization, generalization, higher- and lower-level entity sets, attribute inheritance, and aggregation. The notion of specialization and generalization are covered in the context of object-oriented data models in Section 8.2.2. A full explanation of the other features is beyond the scope of this chapter; we refer readers to [SKS11] for additional information.

8.2.1.2 Representing Data Constraints

In addition to entities and relationships, the E-R model represents certain constraints to which the contents of a database must conform. One important constraint is *mapping cardinalities*, which express the number of entities to which another entity can be associated via a relationship set. Therefore, relationships

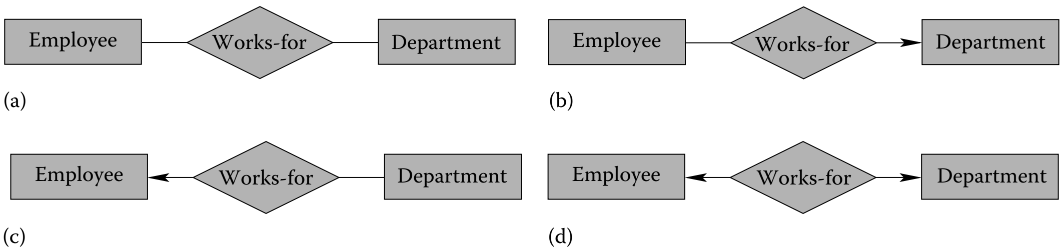

FIGURE 8.5 Relationship cardinalities. (a) Many-to-many relationship. (b) Many-to-one relationship. (c) One-to-many relationship. (d) One-to-one relationship.

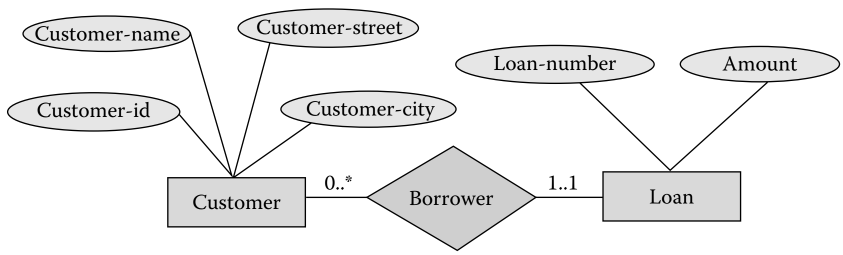

FIGURE 8.6 Cardinality limits on relationship sets.

can be classified as many-to-many, many-to-one, or one-to-one. A many-to-many *works-for* relationship between employee and department exists if a department may have one or more employees and an employee may work for one or more departments. A many-to-one *works-for* relationship between *employee* and *department* exists if a department may have one or more employees but an employee must work for only department. A one-to-one *works-for* relationship exists if a department were required to have exactly one employee, and an employee required to work for exactly one department. In an E-R diagram, an arrow is used to indicate the type of relationship as shown in Figure 8.5. The arrow indicates "exactly one."

E-R diagrams also provide a way to indicate more complex constraints on the number of times each entity participates in relationships in a relationship set. An edge between an entity set and a binary relationship set can have an associated minimum and maximum cardinality, shown in the form $l..h$, where l is the minimum and h the maximum cardinality. A maximum value of 1 indicates that the entity participates in at most one relationship, while a maximum value * indicates no limit.

For example, consider Figure 8.6. The edge between *loan* and *borrower* has a cardinality constraint of 1..1, meaning the minimum and the maximum cardinality are both 1. That is, each loan must have exactly one associated customer. The limit $0..^*$ on the edge from *customer* to *borrower* indicates that a customer can have zero or more loans. Thus, the relationship *borrower* is one to many from *customer* to *loan*.

It is easy to misinterpret the $0..^*$ on the edge between *customer* and *borrower*, and think that the relationship *borrower* is many to one from *customer* to *loan*—this is exactly the reverse of the correct interpretation. In this case, the earlier arrow notation is easier to understand.

If both edges from a binary relationship have a maximum value of 1, the relationship is one-to-one. If we had specified a cardinality limit of $1..^*$ on the edge between *customer* and *borrower*, we would be saying that each customer must have at least one loan.

8.2.1.3 Use of E-R Model in Database Design

A high-level data model, such as the E-R model, serves the database designer by providing a conceptual framework in which to specify, in a systematic fashion, the data requirements of the database users and

how the database will be structured to fulfill these requirements. The initial phase of database design, then, is to characterize fully the data needs of prospective database users. The outcome of this phase will be a *specification of user requirements*. The initial specification of user requirements may be based on interviews with the database users and the designer's own analysis of the enterprise. The description that arises from this design phase serves as the basis for specifying the logical structure of the database.

By applying the concepts of the E-R model, the user requirements are translated into a conceptual schema of the database. The schema developed at this *conceptual design* phase provides a detailed overview of the enterprise. Stated in terms of the E-R model, the conceptual schema specifies all entity sets, relationship sets, attributes, and mapping constraints. The schema can be reviewed to confirm that all data requirements are indeed satisfied and are not in conflict with each other. The design can also be examined to remove any redundant features. The focus at this point is on describing the data and their relationships rather than on physical storage details.

A fully developed conceptual schema also indicates the functional requirements of the enterprise. In a *specification of functional requirements*, users describe the kinds of operations (or transactions) that will be performed on the data. Example operations include modifying or updating data, searching for and retrieving specific data, and deleting data. A review of the schema for meeting functional requirements can be made at the conceptual design stage.

The process of moving from a conceptual schema to the actual implementation of the database involves two final design phases. In the *logical design* phase, the high-level conceptual schema is mapped onto the implementation data model of the database management system (DBMS). In the next section, we discuss how a relational schema can be derived from an E-R design. The resulting DBMS-specific database schema is then used in the subsequent *physical design* phase, in which the physical features of the database are specified. These features include the form of file organization and the internal storage structures.

Because the E-R model is extremely useful in mapping the meanings and interactions of real-world enterprises onto a conceptual schema, a number of database design tools draw on E-R concepts. Further, the relative simplicity and pictorial clarity of the E-R diagramming technique may well account in large part for the widespread use of the E-R model.

8.2.1.4 Deriving a Relational Database Design from the E-R Model

A database that conforms to an E-R diagram can be represented by a collection of relational tables. For each entity set and each relationship set in the database, there is a unique table that is assigned the name of the corresponding entity set or relationship set. Each table has a number of columns that, again, have unique names. The conversion of database representation from an E-R diagram to a table format is the basis for deriving a relational database design.

The column headers of a table representing an entity set correspond to the attributes of the entity, and the primary key of the entity becomes the primary key of the relation. The column headers of a table representing a relationship set correspond to the primary key attributes of the participating entity sets, and the attributes of the relationship set. Rows in the table can be uniquely identified by the combined primary keys of the participating entity sets. For such a table, the primary keys of the participating entity sets are *foreign keys* of the table. The rows of the tables correspond to individual members of the entity or relationship set.

Tables 8.1 through 8.3 show instances of tables that correspond, respectively, to the *customer* and *loan* entity sets, the *borrower* relationship set, of Figure 8.6.

The full set of steps to convert an E-R design to a well-designed set of tables is presented in [SKS11].

8.2.2 Object-Oriented Model

The object-oriented data model is an adaptation of the object-oriented programming paradigm to database systems. The object-oriented approach to programming was first introduced by the language Simula 67, which was designed for programming simulations and advanced further by Smalltalk.

Today, C++ and Java have become the most widely known object-oriented programming languages, and most application development is done in these or other object-oriented languages. The model is based on the concept of encapsulating data, and code that operates on those data, in an object.

In this section, we present an overview of the concepts of object-oriented application development and how they are used in database systems.

8.2.2.1 Basics

Like the E-R model, the object-oriented model is based on a collection of objects. Entities, in the sense of the E-R model, are represented as *objects* with attribute values represented by *instance variables* within the object. The value stored in an instance variable may itself be an object. Objects can contain objects to an arbitrarily deep level of nesting. At the bottom of this hierarchy are objects such as integers, character strings, and other data types that are built into the object-oriented language and serve as the foundation of the object-oriented model. The set of built-in object types varies among languages.

Usually, the data within an object are private to that object and manipulated only by procedures (usually called methods) within that object. Therefore, the internal representation of an object's data need not influence the implementation of any other object; all access to data within an object is via publicly accessible methods for that object. This encapsulation of code and data has proven useful in developing higher modular systems.

Unless the developer decides to make some parts of the object structure public, the only way in which one object can access the data of another object is by invoking a method of that other object. Thus, the call interface of the methods of an object defines its externally visible part. The internal parts of the object—the instance variables and method code—are not visible externally. The result is two levels of data abstraction.

To illustrate the concept, consider an object representing a bank account. Such an object contains instance variables *account-number* and *account-balance*, representing the account number and account balance. It contains a method *pay-interest*, which adds interest to the balance. Assume that the bank had been paying 4% interest on all accounts but now is changing its policy to pay 3% if the balance is less than $1000 or 4% if the balance is $1000 or greater. Under most data models, this would involve changing code in one or more application programs. Under the object-oriented model, the only change is made within the *pay- interest* method. The external interface to the object remains unchanged.

8.2.2.2 Classes

Objects that contain the same types of values and the same methods are grouped together into *classes*. A class may be viewed as a type definition for objects. This combination of data and code into a type definition is similar to the programming language concept of abstract data types. Thus, all *employee* objects may be grouped into an *employee* class. Classes themselves can be grouped into a hierarchy of classes; for example, the *employee* class and the *customer* classes may be grouped into a *person* class. The class *person* is a *superclass* of the *employee* and *customer* classes, since all objects of the *employee* and *customer* classes also belong to the *person* class. Superclasses are also called *generalizations*. Correspondingly, the *employee* and *customer* classes are *subclasses* of *person*; subclasses are also called *specializations*.

The hierarchy of classes allows sharing of common methods. It also allows several distinct views of objects: an employee, for an example, may be viewed either in the role of person or employee, whichever is more appropriate.

8.2.2.3 Object-Oriented Database Programming Languages

There are two approaches to creating an object-oriented database language: the concepts of object orientation can be added to existing database languages, or existing object-oriented languages can be extended to deal with databases by adding concepts such as persistence and collections. Object-relational database systems take the former approach. Persistent programming languages follow the latter approach.

Any persistent programming language must have a mechanism for making objects persist; those not designated persistent are *transient* and vanish when the program terminates. Among the approaches to persistence are

- *Persistence by class*. A class may be declared persistent, making all objects of such classes persistent. Objects of all other classes are transient. This approach is simple but lacks flexibility.
- *Persistence by creation*. At the time of object creation, the program may choose to declare the object persistent; otherwise it is transient.
- *Persistence by marking*. All objects are transient at the time they are created. However, at any point prior to program termination, an object can be marked as persistent. This approach improves on persistence by creation in that the decision on persistence can be deferred beyond creation time. It has the disadvantage of making it less clear to the developer which objects are in fact persistent.
- *Persistence by reachability*. Objects may be declared to be persistent. Not only are those objects persistent but also those objects reachable from those objects by a sequence of object references. This makes it easy to create a persistent data structure simply by making its root persistent, but it makes it more expensive for the system to determine which objects are persistent.

The Object Data Management Group (ODMG) developed standards for integrating persistence support into several programming languages such as C++ and Java. The Java Database Objects (JDO) standard provided a similar functionality, with tighter integration with Java. However, both these standards are no longer extensively used.

Instead, a new approach called *Object-Relational Mapping* (*ORM*) has found widespread acceptance. In this approach, a schema designer provides an object-oriented data model, along with a specification of how the data are to be mapped to a relational model. Library functions provided by ORM systems convert data from the relational representation used for storage to an object-oriented representation stored in memory. Updates to the in-memory object-oriented representation are translated back into updates on the underlying relational model. ORM systems provide an API to fetch objects based on a primary key; in addition, when the program traverses a reference from a previous fetched object, the referenced object is transparently fetched from the database in case it had not been fetched earlier. These features are ideally suited for online transaction processing systems. ORM systems also typically provide a query language for bulk data processing, with queries expressed in terms of the object-oriented data mode. The Hibernate ORM system is currently the most widely used ORM implementation.

The alternative to persistent programming languages is to leave persistence to the database system and provide ways for standard programming language applications to access the database. The most popular of these are ODBC for C and C++ programs and JDBC for Java.

8.2.3 Object-Relational Data Models

Object-relational data models extend the relational data model by providing a richer type system that allows representation of instance variables and methods. In many implementations, stored procedures serve in place of methods.

The rigid structure of relations arose historically from the use of fixed length records, first on punched cards and later in early file systems. A more general model of relations would allow set-valued and relation-valued attributes. Such concepts were proposed in the 1980s [RK87:Design], but have only more recently appeared in practice. SQL has implemented this concept through *structured types*. Constructs are added to relational query languages such as SQL to deal with the added data types. The extended type systems allow attributes of tuples to have complex types including non-atomic values such as nested relations. Such extensions attempt to preserve the relational foundations, in particular the declarative access to data, while extending the modeling power.

As an example, consider a *person* entity whose attributes include name, which consists of first- and last-name) and address, which consists of street, city, and postal code. This can be expressed as

```
create type Name as
   (firstname varchar(20),
   lastname varchar(20))
   final;
create type Address as
   (street varchar(20),
   city varchar(20),
   zipcode varchar(9))
   not final;
create table Person (
   name Name,
   address Address,
   dateOfBirth date);
```

Observe that the *Person* table has two attributes, *Name* and *Address* that themselves have substructures. Such data types were specifically disallowed in early relation systems and, indeed, *first normal form* was defined to specify that relations have only atomic, indivisible values. Clearly, then, relations such as *Person* are non-first-normal-form relations.

In addition to allowing tuples within tuples as in our example, SQL allows attributes to hold arrays and multisets (sets in which values may occur multiple times). These features now give SQL the full modeling capability of earlier nested relational model proposals.

Data types, like *Address* in our example, that have the *not final* specification can have *subtypes* defined under them, allowing the definition of subclasses. Finally, data types may have methods defined on them that, such as methods in an object-oriented language, operate on an instance (object) of these types. In addition to object-oriented data-modeling features, SQL supports an imperative extension of the basic SQL query language, providing features such as for and while loops, if-then-else statements, procedures, and functions. SQL also supports references to objects; references must be to objects of a particular type, which are stored as tuples of a particular relation. Objects, however, do not have an independent existence, they correspond to tuples in a relation.

Relations are allowed to form an inheritance hierarchy; each tuple in a lower level relation must correspond to a unique tuple in a higher-level relation that represents information about the same object. Inheritance of relations provides a convenient way of modeling roles, where an object can acquire and relinquish roles over a period of time.

SQL support this via table inheritance; if *r* is a subtable of *s*, the type of tuples of *r* must be a subtype of the type of tuples of *s*. Every tuple present in *r* is implicitly (automatically) present in *s* as well. A query on *s* would find all tuples inserted directly to *s* as well as tuples inserted into *r*; however, only the attributes of table *s* would be accessible, even for the *r* tuples. Thus subtables can be used to represent specialization/generalization hierarchies. However, while subtables in SQL can be used to represent disjoint specializations, where an object cannot belong to two different subclasses of a particular class, they cannot be used to represent the general case of overlapping specialization.

The combination of these features gives SQL a rich set of object-oriented features. In practice, however, the exact syntax of these constructs varies from the published standard. The reason for this is that, prior to object-relational features being added to the SQL standard, many commercial database systems incorporated their own proprietary object-relational extensions into their SQL implementations. While these all offer similar computational and modeling capabilities, the syntactic distinctions create problems when porting database designs across database systems. As a result, object-relational extensions of SQL are not widely used in practice.

Object-relational database systems (that is, database systems based on the object-relation model) provide a convenient migration path for users of relational databases who wish to use object-oriented features. Complex types such as nested relations are useful to model complex data in many applications. Object-relational systems combine complex data based on an extended relational model with object-oriented concepts such as object identity and inheritance.

8.3 Modeling Nested Structures

We have already seen how SQL has been extended over the years to allow representation of nested relational structures. There are other models in wide use for representing nested structures, including XML and JSON. These models are particularly useful when several applications need to share data, but do not all use the same database. In the section, we show how these models can be used in conjunction with a database system, but we do not go into the full feature set of these models.

8.3.1 XML

Extensible Markup Language (XML) was not originally conceived as a database technology. In fact, like the *Hyper-Text Markup Language (HTML)* on which the world wide web is based, XML has its roots in document management. However, unlike HTML, XML can represent database data, as well as many other kinds of structured data used in business applications.

The term *markup* in the context of documents refers to anything in a document that is not intended to be part of the printed output. For the family of markup languages that includes HTML and XML, the markup takes the form of *tags* enclosed in angle-brackets, <>. Tags are used in pairs, with <tag> and </tag> delimiting the beginning and the end of the portion of the document to which the tag refers.

Unlike HTML, XML does not prescribe the set of tags allowed, and the set may be specialized as needed. This feature is the key to XML's major role in data representation and exchange, whereas HTML is used primarily for document formatting.

For example, in our running banking application, account and customer information can be represented as part of an XML document as in Figure 8.7. Observe the use of tags such as `account` and `account-number`. These tags provide context for each value and allow the semantics of the value to be identified. The contents between a start tag and its corresponding end tag is called an *element*.

Compared to storage of data in a database, the XML representation is inefficient, since tag names are repeated throughout the document. However, in spite of this disadvantage, an XML representation has significant advantages when it is used to exchange data:

- First, the presence of the tags makes the message *self-documenting*; that is, a schema need not be consulted to understand the meaning of the text.
- Second, the format of the document is not rigid. For example, if some sender adds additional information, such as a tag `last-accessed` noting the last date on which an account was accessed, the recipient of the XML data may simply ignore the tag. The ability to recognize and ignore unexpected tags allows the format of the data to evolve over time, without invalidating existing applications.
- Third, elements can be nested inside other elements, to any level of nesting. Figure 8.8 shows a representation of the bank information from Figure 8.7, but with `account` elements nested within `customer` elements.
- Finally, since the XML format is widely accepted, a wide variety of tools are available to assist in its processing, including browser software and database tools.

Just as SQL is the dominant *language* for querying relational data, XML is becoming the dominant *format* for data exchange.

```
<bank>
  <account>
    <account-number> A-101 </account-number>
    <branch-name> Downtown </branch-name>
    <balance> 500 </balance>
  </account>
  <account>
    <account-number> A-102 </account-number>
    <branch-name> Perryridge </branch-name>
    <balance> 400 </balance>
  </account>
  <account>
    <account-number> A-201 </account-number>
    <branch-name> Brighton </branch-name>
    <balance> 900 </balance>
  </account>
  <customer>
    <customer-name> Johnson </customer-name>
    <customer-street> Alma </customer-street>
    <customer-city> Palo Alto </customer-city>
  </customer>
  <customer>
    <customer-name> Hayes </customer-name>
    <customer-street> Main </customer-street>
    <customer-city> Harrison </customer-city>
  </customer>
  <depositor>
    <account-number> A-101 </account-number>
    <customer-name> Johnson </customer-name>
  </depositor>
  <depositor>
    <account-number> A-201 </account-number>
    <customer-name> Johnson </customer-name>
  </depositor>
  <depositor>
    <account-number> A-102 </account-number>
    <customer-name> Hayes </customer-name>
  </depositor>
</bank>
```

FIGURE 8.7 XML representation of bank information.

In addition to elements, XML specifies the notion of an *attribute*. For example, the type of an account is represented in the following as an attribute named `acct-type`.

```
…
    <account acct-type = "checking">
       <account-number> A-102 </account-number>
       <branch-name> Perryridge </branch-name>
       <balance> 400 </balance>
    </account>
…
```

The attributes of an element appear as *name* = *value* pairs before the closing ">" of a tag. Attributes are strings, and do not contain markup. Furthermore, an attribute name can appear only once in a given tag, unlike subelements, which may be repeated.

Note that in a document construction context, the distinction between subelement and attribute is important—an attribute is implicitly text that does not appear in the printed or displayed document.

```
<bank-1>
  <customer>
    <customer-name> Johnson </customer-name>
    <customer-street> Alma </customer-street>
    <customer-city> Palo Alto </customer-city>
    <account>
      <account-number> A-101 </account-number>
      <branch-name> Downtown </branch-name>
      <balance> 500 </balance>
    </account>
    <account>
      <account-number> A-201 </account-number>
      <branch-name> Brighton </branch-name>
      <balance> 900 </balance>
    </account>
  </customer>
  <customer>
    <customer-name> Hayes </customer-name>
    <customer-street> Main </customer-street>
    <customer-city> Harrison </customer-city>
    <account>
      <account-number> A-102 </account-number>
      <branch-name> Perryridge </branch-name>
      <balance> 400 </balance>
    </account>
  </customer>
</bank-1>
```

FIGURE 8.8 Nested XML representation of bank information.

However, in database and data exchange applications of XML, this distinction is less relevant, and the choice of representing data as an attribute or a subelement is often arbitrary.

The *document type definition* (DTD) is an optional part of an XML document. The main purpose of a DTD is much like that of a schema: to constrain and type the information present in the document. However, the DTD does not in fact constrain types in the sense of basic types like integer or string. Instead, it only constrains the appearance of subelements and attributes within an element. The DTD is primarily a list of rules for what pattern of subelements appears within an element.

The *XMLSchema* language plays the same role as DTDs, but is more powerful in terms of the types and constraints it can specify. The *XPath* and *XQuery* languages are used to query XML data. The XQuery language can be thought of as an extension of SQL to handle data with nested structure, although its syntax is different from that of SQL.

Many database systems store XML data by mapping them to relations. Unlike in the case of E-R diagram to relation mappings, the XML to relation mappings are more complex and done transparently. Users can write queries directly in terms of the XML structure, using XML query languages.

8.3.2 JSON

JavaScript Object Notation (JSON), such as XML, is a text-based format for data exchange. Whereas XML is based on a pairing of tags and values, JSON is based on a nested collection of pairings of *names* and values. A simple name–value pair takes the form

```
n:v
```

where

n is a name
v is a value

```
"bank-1" : {
   "customer" : {
      "customer-name" : Johnson,
      "customer-street" : Alma,
      "customer-city" : Palo Alto,
      "account" : {
         "account-number" : A-101,
         "branch-name" : Downtown,
         "balance" : 500 },
      "account" : {
         "account-number" : A-201,
         "branch-name" : Brighton,
         "balance" : 900 },
      },
   "customer" : {
      "customer-name" : Hayes,
      "customer-street" : Main,
      "customer-city" : Harrison,
      "account" : {
         "account-number" : A-102,
        "branch-name" : Perryridge,
         "balance" : 400 }
      }
   }
```

FIGURE 8.9 JSON representation of bank information.

The name *n* is a quoted string (in double quotes), and the value *v* is one of the JSON basic types (number, string, Boolean), or a composite type (array elements listed in square brackets separated by commas), or object (set of name–value pairs, listed within set brackets and separated by commas). The bank information we listed in XML in Figure 8.7 appears in JSON format in Figure 8.9. It is easy to note the similarity between the JSON and the XML representations of our sample bank data. JSON's representation is somewhat more compact.

Because JSON syntax is compatible with the popular scripting language JavaScript, JSON data are easily manipulated in JavaScript. JSON Schema permits specification of a schema for JSON data. Tools are available to test whether input JSON data are compatible with a given schema.

8.4 Temporal Data

Suppose we retain data in our bank showing not only the address of each customer but also all former addresses of which the bank is aware. We may then ask queries such as "Find all customers who lived in Princeton in 1981." In this case, we may have multiple addresses for customers. Each address has an associated start and end date, indicating when the customer was resident at that address. A special value for the end date, e.g., null, or a value well into the future such as 9999-12-31, can be used to indicate that the customer is still resident at that address.

In general, *temporal data* are data that have an associated time interval during which they are *valid*. (There are other models of temporal data that distinguish between *valid time* and *transaction time*, the latter recording when a fact was recorded in the database. We ignore such details for simplicity.) We use the term *snapshot* of data to mean the value of the data at a particular point in time. Thus a snapshot of customer data gives the values of all attributes, such as address, of customers at a particular point in time.

Modeling temporal data is a challenging problem for several reasons. For example, suppose we have a *customer* entity with which we wish to associate a time-varying address. To add temporal information to an address, we would then have to create a multivalued attribute, each of whose values

is a composite value containing an address and a time interval. In addition to time-varying attribute values, entities may themselves have an associated valid time. For example, an account entity may have a valid time from the date it is opened to the date it is closed. Relationships too may have associated valid times. For example, the *depositor* relationship between a customer and an account may record when the customer became an owner of the account. We would thus have to add valid time intervals to attribute values, entities, and relationships. Adding such detail to an E-R diagram makes it very difficult to create and to comprehend. There have been several proposals to extend the E-R notation to specify in a simple manner that an attribute or relationship is time-varying, but there are no accepted standards.

Consider the constraint that a department has only one manager, which could be stated as "department functionally determines manager." Such a constraint is expected to hold at a point in time, but surely cannot be expected to hold across time, since a department may have different managers at different points in time. Functional dependencies that hold at a particular point in time are called temporal functional dependencies; data in every snapshot of the database must satisfy the functional dependency.

8.5 Stream Data

The discussion of data models to this point is based on the assumption that there is a collection of data to model and store. Another view of data is that of a *stream*, in which data arrive continuously and in a sufficiently large volume that all of the data cannot be stored in the system. When new data arrive in the stream, the system uses that input to update a set of pre-defined computations. These could be simple aggregates (such as sum) or more complicated queries expressed in a SQL-like language designed for streams. These are sometimes referred to as *continuous queries*. A continuous query has a set of associated tuples at any point in time; and whenever the set of tuples changes, the system outputs either a tuple insertion or tuple deletion event. Thus, the output of a continuous query on a data stream is itself a data stream.

Because all prior data entering from the stream cannot be stored in the system, any computation done by the system is usually restricted to a limited amount of stream data. That restricted amount of data is called a *window* and stream query languages permit users to specify the maximum size of a window and how window boundaries are computed.

Stream data are becoming increasing common. Examples include telecommunication billing systems in which each billable event (call, text message, etc.) requires a price calculation and bill update, sensor networks in which a large volume of deployed sensors transmit data to a collection site, and ground stations for satellite data that need to collect and process data in real time as they arrive from the satellite.

The data in a stream could then be modeled, for example, using the relational data model, and one could view handling of data streams as a lower-level physical design issue. However, designers of streaming data systems have found it beneficial to model streaming data using a stream data model, which is an extension of the relational model, and to provide operators that convert data between the stream data model and the relational model.

The stream data model extends the relational model by associating a sequence number, typically a timestamp, with each tuple in the data stream. A window operation operates on a data stream, and creates multiple windows, with data in each window being modeled as a relation. There are also operators that take the result of a relational query using a window relation, and create an output stream whose timestamp/sequence number is defined by a timestamp/sequence number associated with the window. More recently, there have been proposals to model streaming data as having a beginning and an end timestamp; the timestamps of a particular tuple corresponding to the period in which the tuple is considered valid.

Further Readings

1. *The Relational model*
   The relational model was proposed by E. F. Codd of the IBM San Jose Research Laboratory in the late 1960s [Cod70]. Following Codd's original paper, several research projects were formed with the goal of constructing practical relational database systems, including System R at the IBM San Jose Research Laboratory (Chamberlin et al. [CAB+81]), Ingres at the University of California at Berkeley (Stonebraker [Sto86b]), and Query-by-Example at the IBM T. J. Watson Research Center (Zloof [Zlo77]).

   General discussion of the relational data model appears in most database texts, including Date [Dat00], Ullman [Ull88], ElMasri and Navathe [EN11], Ramakrishnan and Gehrke [RG02], and Silberschatz et al. [SKS11]. Textbook descriptions of the SQL-92 language include Date and Darwen [DD97] and Melton and Simon [MS93].

   Textbook descriptions of the network and hierarchical models, which predated the relational model, can be found on the website http://www.db-book.com (this is the website of the text by Silberschatz et al. [SKS11]).
2. *The object-based models*
   a. The entity-relationship model: The entity-relationship data model was introduced by Chen [Che76]. Basic textbook discussions are offered by ElMasri and Navathe [EN11], Ramakrishnan and Gehrke [RG02], and Silberschatz et al. [SKS11]. Various data manipulation languages for the E-R model have been proposed, though none is in widespread commercial use. The concepts of generalization, specialization, and aggregation were introduced by Smith and Smith [SS77].
   b. *Object-oriented models*: Numerous object-oriented database systems were implemented as either products or research prototypes. Some of the commercial products include ObjectStore, Ontos, Orion, and Versant. More information on these may be found in overviews of object-oriented database research, such as Kim and Lochovsky [KL89], Zdonik and Maier [ZM90], and Dogac et al. [DOBS94]. The ODMG standard is described by Cattell [Cat00]. Information about the Hibernate object-relational mapping system can be found at http://www.hibernate.org.
   c. *Object-relational models*: The nested relational model was introduced in [Mak77] and [JS82]. Design and normalization issues are discussed in [OY87], [RK87], and [MNE96]. POSTGRES ([SR86] and [Sto86a]) was an early implementation of an object-relational system. Commercial databases such as IBM DB2, Informix, and Oracle support various object-relational features of SQL:1999. Refer to the user manuals of these systems for more details.

   Melton et al. [MSG01] and Melton [Mel02] provide descriptions of SQL:1999; [Mel02] emphasizes advanced features, such as the object-relational features, of SQL:1999. Date and Darwen [DD00] describes future directions for data models and database systems.
3. *Nested structures*
   The World Wide Web Consortium (W3C) acts as the standards body for web-related standards, including basic XML and all the XML-related languages such as XPath, XSLT, and XQuery. A large number of technical reports defining the XML-related standards are available at http://www.w3c.org.

   A large number of books on XML are available in the market. These include [CSK01], [CRZ03], and [E+00].

   The JSON data interchange format is defined in IETF RFC 4627, available online at http://www.ietf.org/rfc/rfc4627.
4. *Stream data*
   Several systems have been built to handle data streams, including Aurora, StreamBase, Stanford STREAMS, and Oracle CEP. The Aurora data stream management system is described in [ACc+03].

[MWA+03] provides an overview of many issues in managing data streams, in the context of the Stanford STREAMS system. The CQL query language, described in [ABW06], was developed as part of the Stanford STREAMS project and is used in the Oracle Complex Event Processing (CEP) system. The StreamBase system (http://www.streambase.com) implements an SQL-based query language, which has some similarities to the CQL language, but differs in several respects. [JMS+08] is a step toward a standard for SQL on data streams.

5. *Knowledge representation models*
   The area of knowledge representation, which has been widely studied in the AI community, aims at modeling not only data but also knowledge in the form of rules. A variety of knowledge representation models and languages have been proposed; Brachman and Levesque [BL04] provide detailed coverage of the area of knowledge representation and reasoning. We note that one of the knowledge representation models, called Resource Description Framework, or RDF for short, has been widely used in recent years for modeling semistructured data. RDF is an example of a graph-based data model, where nodes represent concepts, entities, and values, while labeled edges specify relationships between the concepts/entities/values. See http://www.w3.org/RDF for more information on RDF.

Glossary

Attribute: (1) A descriptive feature of an entity or relationship in the entity-relationship model; (2) the name of a column header in a table, or, in relational-model terminology, the name of a domain used to define a relation.

Class: A set of objects in the object-oriented model that contain the same types of values and the same methods; also, a type definition for objects.

Data model: A data model is a collection of conceptual tools for describing the real-world entities to be modeled in the database and the relationships among these entities.

Element: The contents between a start tag and its corresponding end tag in an XML document.

Entity: A distinguishable item in the real-world enterprise being modeled by a database schema.

Foreign key: A set of attributes in a relation schema whose value identifies a unique tuple in another relational schema.

Functional dependency: A rule stating that given values for some set of attributes, the value for some other set of attributes is uniquely determined. X functionally determines Y if whenever two tuples in a relation have the same value on X, they must also have the same value on Y.

Generalization: A super-class; an entity set that contains all the members one or more specialized entity sets.

Instance variable: Attribute values within objects.

Key: (1) A set of attributes in the entity relationship model that serves as a unique identifier for entities. Also known as *super-key*. (2) a set of attributes in a relation schema that functionally determines the entire schema. (3) *candidate key*—a minimal key; that is, a super-key for which no proper subset is a super-key. (4) *primary key*—a candidate key chosen as the primary means of identifying/accessing an entity set, relationship set, or relation.

Message: The means by which an object invokes a method in another object.

Method: Procedures within an object that operate on the instance variables of the object and/or send messages to other objects.

Normal form: A set of desirable properties of a schema. Examples include the Boyce–Codd normal form and the third normal form.

Object: Data and behavior (methods) representing an entity.

Persistence: The ability of information to survive (persist) despite failures of all kinds, including crashes of programs, operating systems, networks, and hardware.

Relation: (1) A subset of a Cartesian product of domains. (2) informally, a table.

Relation schema: A type definition for relations consisting of attribute names and a specification of the corresponding domains.

Relational algebra: An algebra on relations; consists of a set of operations, each of which takes as input one or more relations and returns a relation, and a set of rules for combining operations to create expressions.

Relationship: An association among several entities.

Subclass: A class that lies below some other class (a superclass) in a class inheritance hierarchy; a class that contains a subset of the objects in a superclass.

Subtable: A table such that (a) its tuples are of a type that is a subtype of the type of tuples of another table (the supertable), and (b) each tuple in the subtable has a corresponding tuple in the supertable.

Specialization: A subclass; an entity set that contains a subset of entities of another entity set.

Tuning Database Design for High Performance

Philippe Bonnet
IT University of Copenhagen

Dennis Shasha
New York University

9.1 Introduction

In fields ranging from arbitrage to sensor processing, speed of access to data can determine success or failure. Database tuning is the activity of making a database system run faster. Like optimization activities in other areas of computer science and engineering, database tuning must work within certain constraints. Just as compiler optimizers, for example, cannot directly change the underlying hardware but can change register allocations, database tuners cannot change the underlying database management system software, but can make use of the options it offers.

The database administrator in charge of tuning can, for example, modify the design of tables, select new indexes, rearrange transactions, tamper with the operating system, or buy hardware. The goals are to increase throughput and reduce response time. In our personal experience, tuning efforts can have dramatic effects, e.g., reduce a query time from nine hours to 15 seconds.

Further, interactions between database components and the nature of the bottlenecks change with technology. For example, hard drives have been used as secondary storage since the advent of relational database systems; nowadays, only solid state drives (SSD) offer the high-performance throughput needed to match the speed of processing units in a balanced system. In SSDs, sequential IOs are not so much faster than random IOs (which is the case for disks).

Tuning, then, is for well-informed generalists. This chapter introduces a principled foundation for tuning, focusing on principles that have been robust for years and promise to still hold true for years to come. We include experiments from specific commercial and free database systems, which will become obsolete much faster.

9.2 Underlying Principles

To understand the principles of tuning, you must understand the two main kinds of database applications and what affects performance.

9.2.1 What Databases Do

At a high level of abstraction, databases are used for two purposes: on-line transaction processing and decision support. **On-line transaction processing** typically involves access to a small number of records, generally to modify them. A typical such transaction records a sale or updates a bank account. These transactions use indexes to access their few records without scanning through an entire table. **E-commerce** applications are modern examples of OLTP applications. It seems that potential e-customers will abandon a site if they have to wait more than for a google search.

Decision support queries, by contrast, read many records often from a **data warehouse**, compute an aggregate result, and sometimes apply that aggregate back to an individual level. Typical decision support queries are "find the total sales of widgets in the last quarter in the northeast" or "calculate the available inventory per unit item." Sometimes the results are actionable as in "find frequent flyer passengers who have encountered substantial delays in their last few flights and send them free tickets and an apology."

Data mining is, in practice, best done outside the database management system, though it may draw samples from the database. In so doing, it issues decision support queries.

9.2.2 Performance Spoilers

Having divided the database applications into two broad areas, we can now discuss what slows them down.

1. *Random vs. sequential disk accesses*: On hard disk drives, sequential disk bandwidth is between one and two orders of magnitude (10–100 times) greater than random-access disk bandwidth. On SSDs, there is no intrinsic difference between the throughput of sequential and random reads because read performance depends only on the degree of parallelism achieved within the SSD. Depending on the SSD model, the relative performance of sequential and random reads will vary, but not much. Thus on hard drives, many sequential IOs might be much faster than few random IOs; while on SSDs fewer IOs is always better. Concretely, index accesses tend to be random whereas scans are sequential. Thus, on hard disks, removing an index may sometimes improve performance, because the index used performs random reads and behaves poorly. While on SSDs, indexed accesses are better than scans provided they result in fewer IOs.
2. *Lack of parallelism*: Modern computer systems support parallelism in processing (e.g., multicore and/or graphics processors), storage (controllers, disks, and SSDs). Poor layout and operating system choices may inhibit parallelism.
3. *Imprecise data searches*: These occur typically when a selection retrieves a small number of rows from a large table, yet must search the entire table to find those data. Establishing an index may help in this case, though other actions, including reorganizing the table, may also have an effect.
4. *Many short data interactions, either over a network or to the database*: This may occur, for example, if an object-oriented application views records as objects and assembles a collection of objects by accessing a database repeatedly from within a "for" loop rather than as a bulk retrieval.
5. Delays due to lock conflicts.

These occur either when update transactions execute too long or when several transactions want to access the same datum, but are delayed because of locks. A typical example might be a single variable

that must be updated whenever a record is inserted. In the following example, the COUNTER table contains the next value which is used as a key when inserting values in the ACCOUNT table.

```
begin transaction
   NextKey: = select nextkey from COUNTER;
   insert into ACCOUNT values (nextkey, 100, 200);
   update COUNTER set nextkey = NextKey + 1;
end transaction
```

When the number of such transactions issued concurrently increases, COUNTER becomes a bottleneck because all transactions read and write the value of next key. This problem is only amplified by the need to achieve a high degree of parallelism.

As mentioned in the introduction, avoiding performance problems requires changes at all levels of a database system. We will discuss tactics used at several of these levels and their interactions—hardware, concurrency control subsystem, indexes, and conceptual level. There are other levels such as recovery and query rewriting that we mostly defer to Ref. [4].

9.3 Best Practices

Understanding how to tune each level of a database system requires understanding the factors leading to good performance at that level. Each of the following subsections discusses these factors before discussing tuning tactics.

9.3.1 Tuning Hardware

Each processing unit consists of one or more processors, one or more disks, and some memory. Assuming a high-end 180-GIPS (billion instructions per second) processor, the CPU will become the bottleneck for on-line transaction-processing applications when it is attached to 1 high-end SSDs, 10 mid-range SSDs, or 7,200 hard disks (counting 500,000 instructions per random IO issued by the database system and 400,000 random IO per seconds on a high-end SSD, 40,000 random IO per second on a mid range SSD, and 50 random IO per second on a high-end hard disk).

Decision-support queries, by contrast, often entail massive scans of a table. In theory, a 180-GIPS processor is saturated when connected to 1 high-end SSD, 5 mid-range SSDs, or 36 hard disks (counting 500,000 instruction per sequential IO and 1 million sequential IO per second for high-end SSD, 100,000 sequential IO per second for mid-range SSDs, and 10,000 IO per second for hard disks). A few years ago, the system bus was the bottleneck when reading sequentially from several disks. Nowadays, a commonplace PCIe system bus of 5 GT/s (Giga Transfers per second) is not saturated by the aggregated bandwidth of 10 SSDs. The problem is to find enough connectors on the system bus.

Note that a 180 GIPS processor relies on tens of hardware threads to deliver such throughput. Each core delivers typically 20–30 GIPS. Also the figures mentioned earlier assume that the IO submission rate is high enough to leverage the internal parallelism of the SSDs. Achieving a high IO submission rate is the key objective when tuning a database system on SSD.

Summing up, decision-support sites may need fewer disks per processor than transaction-processing sites for the purposes of matching aggregate disk bandwidth to processor speed.* Note that storing 1 TB of data on hard disk is an order of magnitude cheaper than storing 1 TB of data on a SSD.

* This point requires a bit more explanation. There are two reasons you might need more disks: (1) for disk bandwidth (the number of bytes coming from the disk per second); or (2) for space. Disk bandwidth is usually the issue in on-line transaction processing. Decision support applications tend to run into the space issue more frequently, because scanning allows disks to deliver their optimal bandwidth.

All applications will benefit from a mix of solid state drives for high-performance access and hard disks for inexpensive storage.

Random access memory (RAM) obviates the need to go to disk. Database systems reserve a portion of RAM as a *buffer*. In all applications, the buffer usually holds frequently accessed pages (*hot* pages, in database parlance) including the first few levels of indexes. Increasing the amount of RAM buffer tends to be particularly helpful in on-line transaction applications where disks are the bottleneck, particularly for smaller tables.

The read **hit ratio** in a database is the portion of database reads that are satisfied by the buffer. Hit ratios of 90% or higher are common in on-line transaction applications, but less common in decision support applications. Even in transaction processing applications, hit ratios tend to level off as you increase the buffer size if there is one or more tables that are accessed unpredictably and are much larger than available RAM (e.g., sales records for a large department store).

The decreasing cost of RAM makes it economical to attach 256 GB of RAM to a CPU. As a consequence, mid-sized databases can be manipulated entirely in RAM centrally on a single server, or in a distributed manner across a cluster. From a tuning point of view, the main goal is then to minimize the number of buffer reads on each server and the amount of communication across servers.

9.3.2 Tuning the Virtual Machine

It is today commonplace to rely on virtual machines to manage the hardware resources in a company. As a result, database systems often run within a virtual machine. Tuning the virtual machine to match the needs of the database system has become an important task. While configuring the number of CPUs, the size of the RAM or the number of disks associated to a virtual machine is rather straightforward. The configuration of the disk controllers and of the disk characteristics is a bit more subtle:

- *No host caching*: The database system expects that the IOs it submits are transferred to disk as directly as possible. It is thus critical to disable file system caching on the host for the IOs submitted by the virtual machine.
- *Hardware supported IO virtualization*: A range of modern CPUs incorporate components that speed up access to IO devices through direct memory access and interrupt remapping (i.e., Intel's VT-d and AMD's AMD-vi). Such a feature is important to allow databases executing within a virtual machine to leverage the performance characteristics of high-end SSDs.
- *Statically allocated disk space*: When creating a virtual disk, it is possible to reserve the space physically on disk (static allocation). Alternatively, the virtual disk grows dynamically as required. Static allocation is preferable for database systems. First, the overhead of space reservation is paid only once at disk creation time, not while executing transactions. Second, static allocation guarantees that a disk is mapped on contiguous physical space. This is especially important when using hard disks, because contiguous allocation guarantees that the sequential IOs submitted by a database system on a virtual disk are actually mapped onto sequential IOs on disk.

9.3.3 Tuning the Operating System

The operating system provides the storage and processing abstractions to the database system. More specifically, file system and thread management impact database performance.

9.3.3.1 Thread Management

Processor affinity refers to binding of a given software thread to a specific hardware thread. It allows efficient cache reuse, and avoids context switches. For transactional workloads, the log write can be assigned to a specific hardware thread to guarantee that it can continuously write to the log.

Modern database systems allow a database administrator to dynamically change the priority of the different threads running in the system. Also, the database system implements mechanisms that avoid the priority inversion problem, where a high-level transaction waits for a low-level transaction to release a resource it is waiting for.

9.3.4 Tuning Concurrency Control

As the chapter on Concurrency Control and Recovery in this handbook explains, database systems attempt to give users the illusion that each transaction executes in isolation from all others. The ANSI SQL standard, for example, makes this explicit with its concept of degrees of isolation [3,5]. Full isolation or **serializability** is the guarantee that each transaction that completes will appear to execute one at a time *except that its performance may be affected by other transactions*. This ensures, for example, that in an accounting database in which every update (sale, purchase, etc.) is recorded as a double-entry transaction, any transaction that sums assets, liabilities, and owners' equity will find that assets equal the sum of the other two. There are less stringent notions of isolation that are appropriate when users do not require such a high degree of consistency.

The concurrency-control algorithm in predominant use is two-phase locking, sometimes with optimizations for data structures. Two-phase locking has **read** (or *shared*) and **write** (or *exclusive*) locks. Two transactions may both hold a shared lock on a datum. If one transaction holds an exclusive lock on a datum, however, then no other transaction may hold any lock on that datum; in this case, the two transactions are said to **conflict**. The notion of datum (the basic unit of locking) is deliberately left unspecified in the field of concurrency control, because the same algorithmic principles apply regardless of the size of the datum, whether a page, a record, or a table. The performance may differ, however. For example, record-level locking works much better than table-level locking for on-line transaction processing applications.

Snapshot isolation avoids read locks as it gives each transaction the illusion that it accesses, throughout its execution, the state of the database that was valid when it started. With snapshot isolation read transactions do not conflict with write transactions [9]. However, snapshot isolation does not ensure serializability. For example, consider a transaction T1 that reads value x and writes that value into y. Suppose that T2 reads y and writes that value into x. If x is initially 3 and y is initially 17, then any serial execution will guarantee that x and y are the same at the end. Under snapshot isolation T1 may read x at the same time that T2 reads y, in which case x will have the value 17 at the end and y will have the value 3.

9.3.4.1 Rearranging Transactions

Tuning concurrency control entails trying to reduce the number and duration of conflicts. This often entails understanding application semantics. Consider, for example, the following code for a purchase application of item i for price p for a company in bankruptcy (for which the cash cannot go below 0):

PURCHASE TRANSACTION (p,i)

BEGIN TRANSACTION
if cash < p then roll back transaction
inventory(i): = inventory(i) + p
cash: = cash − p
END TRANSACTION

From a concurrency-control-theoretical point of view, this code does the right thing. For example, if the cash remaining is 100, and purchase P1 is for item i with price 50, and purchase P2 is for item j with price 75, then one of these will roll back.

From the point of view of performance, however, this transaction design is very poor, because every transaction must acquire an exclusive lock on cash from the beginning to avoid deadlock.

(Otherwise, many transactions will obtain shared locks on cash and none will be able to obtain an exclusive lock on cash.) That will make cash a bottleneck and have the effect of serializing the purchases. Since inventory is apt to be large, accessing inventory(i) will take at least one disk access, taking about 5 ms. Since the transactions will serialize on cash, only one transaction will access inventory at a time. This will limit the number of purchase transactions to about 50 per second. Even a company in bankruptcy may find this rate to be unacceptable.

A surprisingly simple rearrangement helps matters greatly:

Redesigned Purchase Transaction (p,i)

```
Begin Transaction
inventory(i): = inventory(i) + p
if cash < p then roll back transaction
else cash: = cash − p
End Transaction
```

Cash is still a hot spot, but now each transaction will avoid holding cash while accessing inventory. Since cash is so hot, it will be in the RAM buffer. The lock on cash can be released as soon as the commit occurs.

Advanced techniques are available that “chop” transactions into independent pieces to shorten lock times further. We refer interested readers to Ref. [4].

9.3.4.2 Living Dangerously

Many applications live with less than full isolation due to the high cost of holding locks during user interactions. Consider the following full-isolation transaction from an airline reservation application:

Airline Reservation Transaction (p,i)

```
Begin Transaction
Retrieve list of seats available.
Reservation agent talks with customer regarding availability.
Secure seat.
End Transaction
```

The performance of a system built from such transactions would be intolerably slow, because each customer would hold a lock on all available seats for a flight while chatting with the reservations agent. This solution does, however, guarantee two conditions: (1) no two customers will be given the same seat, and (2) any seat that the reservation agent identifies as available in view of the retrieval of seats will still be available when the customer asks to secure it.

Because of the poor performance, however, the following is done instead:

Loosely Consistent Airline Reservation Transaction (p,i)

```
Retrieve list of seats available.
Reservation agent talks with customer regarding availability.
Begin Transaction
Secure seat.
End Transaction
```

This design relegates lock conflicts to the secure step, thus guaranteeing that no two customers will be given the same seat. It does allow the possibility, however, that a customer will be told that a seat is available, will ask to secure it, and will then find out that it is gone. This has actually happened to a particularly garrulous colleague of ours.

9.3.5 Indexes

Access methods, also known as **indexes**, are discussed in another chapter. Here we review the basics, then discuss tuning considerations. An **index** is a data structure plus a method of arranging the data tuples in the table (or other kind of collection object) being indexed. Let us discuss the data structure first.

9.3.5.1 Data Structures

Two data structures are most often used in practice: B-trees and Hash structures. Of these, B-trees are used the most often (one vendor's tuning book puts it this way: "When in doubt, use a B-tree"). Here, we review those concepts about B-trees most relevant to tuning.

A **B-tree** (strictly speaking a B + tree) is a balanced tree whose nodes contain a sequence of key–pointer pairs [2]. The keys are sorted by value. The pointers at the leaves point to the tuples in the indexed table).

B-trees are self-reorganizing through operations known as splits and merges (though occasional reorganizations for the purpose of reducing the number of seeks do take place). Further, they support many different query types well: equality queries (find the employee record of the person having a specific social security number), min–max queries (find the highest-paid employee in the company), and range queries (find all salaries between $70,000 and $80,000).

Because an access to disk secondary memory costs about 5 ms if it requires a seek (as index accesses will), the performance of a B-tree depends critically on the number of nodes in the average path from root to leaf. (The root will tend to be in RAM, but the other levels may or not be, and the farther down the tree the search goes, the less likely they are to be in RAM.) The number of nodes in the path is known as the number of levels. One technique that database management systems use to minimize the number of levels is to make each interior node have as many children as possible (1000 or more for many B-tree implementations). The maximum number of children a node can have is called its *fanout*. Because a B-tree node consists of key–pointer pairs, the bigger the key is, the lower the fanout.

For example, a B-tree with a million records and a fanout of 1000 requires three levels (including the level where the records are kept). A B-tree with a million records and a fanout of 10 requires 7 levels. If we increase the number of records to a billion, the numbers of levels increase to 4 and 10, respectively. This is why accessing data through indexes on large keys is slower than accessing data through small keys on most systems.

Hash structures, by contrast, are a method of storing key–value pairs based on a pseudorandomizing function called a *hash function*. The hash function can be thought of as the root of the structure. Given a key, the hash function returns a location that contains either a page address (usually on disk) or a directory location that holds a set of page addresses. That page either contains the key and associated record or is the first page of a linked list of pages, known as an *overflow chain* leading to the record(s) containing the key. (You can keep overflow chaining to a minimum by using only half the available space in a hash setting.)

In the absence of overflow chains, hash structures can answer equality queries (e.g., find the employee with Social Security number 156-87-9864) in one disk access, making them the best data structures for that purpose. The hash function will return arbitrarily different locations on key values that are close but unequal, e.g., Smith and Smythe. As a result, records containing such close keys will likely be on different pages. This explains why hash structures are completely unhelpful for range and min–max queries.

9.3.5.2 Clustering and Sparse Indexes

The data structure portion of an index has pointers at its leaves to either data pages or data records.

- If there is at most one pointer from the data structure to each data page, then the index is said to be **sparse**.
- If there is one pointer to each record in the table, then the index is said to be **dense**.

If records are small compared to pages, then there will be many records per data page and the data structure supporting a sparse index will usually have one less level than the data structure supporting a dense index. This means one less disk access if the table is large. By contrast, if records are almost as large as pages, then a sparse index will rarely have better disk access properties than a dense index.

The main virtue of dense indexes is that they can support certain read queries within the data structure itself in which case they are said to **cover** the query. For example, if there is a dense index on the keywords of a document retrieval system, a query can count the records containing some term, e.g., "derivatives scandals," without accessing the records themselves. (Count information is useful for that application, because queriers frequently reformulate a query when they discover that it would retrieve too many documents.) A secondary virtue is that a query that makes use of several dense indexes can identify all relevant tuples before accessing the data records; instead, one can just form intersections and unions of pointers to data records.

A **clustering index** on an attribute (or set of attributes) X is an index that puts records close to one another if their X-values are *near* one another. What "near" means depends on the data structure. On B-trees, two X-values are near if they are close in their sort order. For example, 50 and 51 are near, as are Smith and Sneed. In hash structures, two X-values are near only if they are identical.

Some systems such as Oracle and InnoDB use an implicit form of clustering called an **index organized table**. This is a table that is clustered on its primary key (or a system-generated row id, if there is no primary key).

Sparse indexes must be clustering, but clustering indexes need not be sparse. In fact, clustering indexes are sparse in some systems (e.g., SQL Server, ORACLE hash structures) and dense in others (e.g., ORACLE B-trees, DB2). Because a clustering index implies a certain table organization and the table can be organized in only one way at a time, there can be at most one clustering index per table.

A *nonclustering index* (sometimes called a *secondary* index) is an index on an attribute (or set of attributes) Y that puts no constraint on the table organization. The table can be clustered according to some other attribute X or can be organized as a heap, as we discuss later. A nonclustering index must be dense, so there is one leaf pointer per record. There can be many nonclustering indexes per table.

A **heap** is the simplest table organization of all. Records are ordered according to their time of entry. That is, new insertions are added to the last page of the data structure. For this reason, inserting a record requires a single page access. Reading a record requires a scan.

A table and the indexes associated with it might be partitioned. Each partition is associated to a file and each file is associated to a disk. This way a table might be accessed in parallel. Indexes are defined on each partition. The dispatching of tuples into partitions is either based on round-robin, on ranges defined on a partitioning attribute, or on a hash function applied on a partitioning attribute.

Nonclustering indexes are useful if each query retrieves significantly fewer records than there are pages in the file. We use the word "significant" for the following reason: a table scan can often save time by reading many pages at a time, provided the table is stored on contiguous tracks. Therefore, on hard disk, if the scan and the index both read all the pages of the table, the scan may complete 100 times faster than if it read one page at a time. On SSD, this ratio is much smaller.

In summary, nonclustering indexes work best if they cover the query. Otherwise, they work well, specially on SSDs, if the average query using the index will access fewer records than there are data pages. Large records and high selectivity both contribute to the usefulness of nonclustering indexes. On hard disks, scans are hard to beat.

9.3.5.3 Data Structures for Decision Support

Decision support applications often entail querying on several, perhaps individually unselective, attributes. For example, "Find people in a certain income range who are female, live in California, buy climbing equipment, and work in the computer industry." Each of these constraints is unselective in itself, but together form a small result. The best all-around data structure for such a situation is the bitmap.

A bitmap is a collection of vectors of bits. The length of each such "bit vector" equals the length of the table being indexed and has a 1 in position i if the ith record of the table has some property. For example a bitmap on state would consist of 50 bit vectors, one for each state. The vector for California would have a 1 for record i if record i pertains to a person from California. In our experiments, bitmaps outperform multidimensional indexes by a substantial margin.

Some decision support queries compute an aggregate, but never apply the result of the aggregate back to individuals. For example, you might want to find the approximate number of Californian women having the properties mentioned earlier. In that case, you can use approximate summary tables as a kind of indexing technique. The Aqua system [1], for example, proposes an approximation based on constructing a database from a random sample of the most detailed table T (sometimes known as the fact table in data warehouse parlance) and then joining that result with the reference tables R1, R2, …, Rn based on foreign key joins.

9.3.5.4 Final Remarks Concerning Indexes

The main point to remember is that the use of indexes is a two-edged sword: we have seen an index reduce the time to execute a query from hours to a few seconds in one application, yet increase batch load time by a factor of 80 in another application. Add them with care.

9.3.6 Tuning Table Design

Table design is the activity of deciding which attributes should appear in which tables in a relational system. The Conceptual Database Design chapter discusses this issue, emphasizing the desirability of arriving at a **normalized** schema. Performance considerations sometimes suggest choosing a nonnormalized schema, however. More commonly, performance considerations may suggest choosing one normalized schema over another or they may even suggest the use of redundant tables.

9.3.6.1 To Normalize or Not to Normalize

Consider the normalized schema consisting of two tables: *Sale*(sale_id, customer_id, product, quantity) and *Customer*(customer_id, customer_location).

If we frequently want sales per customer location or sales per product per customer location, then this table design requires a join on customer_id for each of these queries. A denormalized alternative is to add customer_location to *Sale*, yielding *Sale*(sale_id, customer_id, product, quantity, customer_location) and *Customer*(customer_id, customer_location). In this alternative, we still would need the *Customer* table to avoid anomalies such as the inability to store the location of a customer who has not yet bought anything.

Comparing these two schemas, we see that the denormalized schema requires more space and more work on insertion of a sale. (Typically, the data-entry operator would type in the customer_id, product, and quantity; the system would generate a sale_id and do a join on customer_id to get customer_location.) On the other hand, the denormalized schema is much better for finding the products sold at a particular customer location.

The tradeoff of space plus insertion cost vs. improved speeds for certain queries is the characteristic one in deciding when to use a denormalized schema. Good practice suggests starting with a normalized schema and then denormalizing sparingly.

9.3.6.2 Redundant Tables

The previous example illustrates a special situation that we can sometimes exploit by implementing wholly redundant tables. Such tables store the aggregates we want. For example:

Sale(sale_id, customer_id, product, quantity) *Customer*(customer_id, customer_location) *Customer_Agg* (customer_id, totalquantity) *Loc_Agg* (customer_location, totalquantity). This reduces the query time,

but imposes an update time as well as a small space overhead. The tradeoff is worthwhile in situations where many aggregate queries are issued (perhaps in a data warehouse situation) and an exact answer is required.

9.3.6.3 Tuning Normalized Schemas

Even restricting our attention to normalized schemas without redundant tables, we find tuning opportunities because many normalized schemas are possible. Consider a bank whose *Account* relation has the normalized schema (account_id is the key):

- *Account*(account_id, balance, name, street, postal_code)

Consider the possibility of replacing this by the following pair of normalized tables:

- *AccountBal*(account_id, balance)
- *AccountLoc*(account_id, name, street, postal_code)

The second schema results from **vertical partitioning** of the first (all nonkey attributes are partitioned). The second schema has the following benefits for simple account update transactions that access only the id and the balance:

- A sparse clustering index on account_id of *AccountBal* may be a level shorter than it would be for the *Account* relation, because the name, street, and postal_code fields are long relative to account_id and balance. The reason is that the leaves of the data structure in a sparse index point to data pages. If *AccountBal* has far fewer pages than the original table, then there will be far fewer leaves in the data structure.
- More account_id–balance pairs will fit in memory, thus increasing the hit ratio. Again, the gain is large if *AccountBal* tuples are much smaller than *Account* tuples.

On the other hand, consider the further decomposition:

- *AccountBal*(account_id, balance)
- *AccountStreet*(account_id, name, street)
- *AccountPost*(account_id, postal_code)

Though still normalized, this schema probably would not work well for this application, since queries (e.g., monthly statements, account update) require both street and postal_code or neither. Vertical partitioning, then, is a technique to be used for users who have intimate knowledge of the application.

In recent years, database systems have been designed as **column-stores**, where vertical partitioning is the rule and efficient mechanisms are provided for improving hit ratio both in the database cache and in CPU cache lines, and for minimizing IOs based on efficient column compression. Column stores are well suited for decision support applications in which tables may have hundreds of columns, but each query uses only a few. The benefit then is that only the few relevant columns need to be processed, saving both input/output time and processing time. Further, storing columns separately gives greater opportunities to achieve high compression.

9.4 Tuning the Application Interface

A central tuning principle asserts *start-up costs are high; running costs are low*. When applied to the application interface, this suggests that you want to transfer as much necessary data as possible between an application language and the database per connection. Here are a few illustrations of this point.

9.4.1 Assemble Object Collections in Bulk

Object-oriented encapsulation allows the implementation of one class to be modified without affecting the rest of the application, thus contributing greatly to code maintenance. Encapsulation sometimes is interpreted as "the specification is all that counts." Unfortunately, that interpretation can lead to horrible performance.

The problem begins with the fact that the most natural object-oriented design on top of a relational database is to make records (or sometimes fields) into objects. Fetching one of these objects then translates to a fetch of a record or a field. So far, so good.

But then the temptation is to build bulk fetches from fetches on little objects (the "encapsulation imperative"). The net result is to execute many small queries, each of which goes across the programming language to database system boundary, instead of one large query.

Consider, for example, a system that delivers and stores documents. Each document type (e.g., a report on a customer account) is produced according to a certain schedule that may differ from one document type to another. Authorization information relates document types to users. This gives a pair of tables of the form:

authorized(user, documenttype)
documentinstance(id, documenttype, documentdate)

When a user logs in, the system should say which document instances he or she can see. This can easily be done with the join:

```
select documentinstance.id, documentinstance.documentdate
from documentinstance, authorized
where documentinstance.documenttype = authorized.documenttype
and authorized.user = <input user name>
```

But if each document type is an object and each document instance is another object, then one may be tempted to write the following code:

```
Authorized authdocs = new Authorized();
authdocs.init(<input user name>);
for (Enumeration e = authdocs.elements(); e.hasMoreElements();)
{
   DocInstance doc = new DocInstance();
   doc.init(e.nextElement());
   doc.print();
}
```

This application program will first issue one query to find all the document types for the user (within the init method of Authorized class):

```
select documentinstance.documenttype
from authorized
where authorized.user = <input user name>
```

and then for each such type t to issue the query (within the init method of DocInstance class):

```
select documentinstance.id, documentinstance.documentdate
from documentinstance
where documentinstance.documenttype = t
```

This is much slower than the previous SQL formulation. The join is performed in the application and not in the database server.

The point is not that object-orientation is bad. Encapsulation contributes to maintainability. The point is that programmers should keep their minds open to the possibility that accessing a bulk object (e.g., a collection of documents) should be done directly rather than by forming the member objects individually and then grouping them into a bulk object on the application side.

9.4.2 Art of Insertion

We have spoken so far about retrieving data. Inserting data rapidly requires understanding the sources of overhead of putting a record into the database:

1. As in the retrieval case, the first source of overhead is an excessive number of round trips across the database interface. This occurs if the batch size of your inserts is too small. In fact up to 100,000 rows, increases in the batch size improve performance on most systems.
2. The second reason has to do with the ancillary overhead that an insert causes: updating all the indexes on the table. Even a single index can hurt performance.
3. Finally, the layers of software within a database system can get in the way. Database systems provide bulk loading tools that achieve high performance by bypassing some of the database layers (mostly having to do with transactional recovery) that would be traversed if single row INSERT statements were used. For instance, *SQL* Loader* is a tool that bulk loads data into Oracle databases. It can be configured to bypass the query engine of the database server (using the direct path option).

The SQL Server BULK INSERT command and SQL*Loader allow the user to define the number of rows per batch or the number of kilobytes per batch. The minimum of the two is used to determine how many rows are loaded in each batch. There is a tradeoff between the performance gained by minimizing the transaction overhead in the omitted layers and the work that has to be redone in case a failure occurs.

9.5 Monitoring Tools

When your system is slow, you must figure out where the problem lies. Is it a single query? Is some specific resource misconfigured? Is there insufficient hardware? Most systems offer the following basic monitoring tools [6,7,8]:

1. Time-spent monitors capture for a transaction, or a session the time spent in the different database components. This information allows to identify for a transaction, which component can be tuned to significantly improve performance.
2. Event monitors (sometimes known as Trace Data Viewer or Server Profiler) capture usage measurements (processor usage ratio, disk usage, locks obtained, etc.) throughout the system at the end of each query. It is sometimes hard to differentiate the contribution of the different transactions to the indicators. Also, it is hard to evaluate how a given indicator impacts the performance of a specific transaction.
3. If you have found an expensive query, you might look to see how it is being executed by looking at the query plan. These Plan Explainer tools tell you which indexes are used, when sorts are done and which join ordering is chosen.
4. If you suspect that some specific resource is overloaded, you can check the consumption of these resources directly using operating system commands. This includes the time evolution of processor usage, disk queuing, and memory consumption. Dynamic tracing frameworks are allowed to collect detailed information even in the context of production systems.

9.6 Tuning Rules of Thumb

Often, tuning consists in applying the techniques cited earlier, such as the selection and placement of indexes or the splitting up of transactions to reduce locking conflicts. At other times, tuning consists in recognizing fundamental inefficiencies and attacking them.

1. Simple problems are often the worst. We have seen a situation where the database was very slow because the computer supporting the database was also the mail router. Offloading nondatabase applications is often necessary to speed up database applications.
2. Another simple problem having a simple solution concerns locating and rethinking specific queries. The authors have had the experience of reducing query times by a factor of 10 by the judicious use of outer joins to avoid superlinear query performance.
3. The use of triggers can often result in surprisingly poor performance. Since procedural languages for triggers resemble standard programming languages, bad habits sometimes emerge. Consider, for example, a trigger that loops over all records inserted by an update statement. If the loop has an expensive multitable join operation, it is important to pull that join out of the loop if possible. We have seen another 10-fold speedup for a critical update operation following such a change.
4. There are many ways to partition load to avoid performance bottlenecks in a large enterprise. One approach is to distribute the data across sites connected by wide-area networks. This can result, however, in performance and administrative overheads unless networks are extremely reliable. Another approach is to distribute queries over time. For example, banks typically send out 1/20 of their monthly statements every working day rather than send out all of them at the end of the month.

9.7 Summary and Research Results

Database tuning is based on a few principles and a body of knowledge. Some of that knowledge depends on the specifics of systems (e.g., which index types each system offers), but most of it is independent of version number, vendor, and even data model (e.g., hierarchical, relational, or object-oriented). This chapter has attempted to provide a taste of the principles that govern effective database tuning.

Various research and commercial efforts have attempted to automate the database tuning process [10]. Among the most successful is the tuning wizard offered by Microsoft's SQL server. Given information about table sizes and access patterns, the tuning wizard can give advice about index selection among other features. Tuners would do well to exploit such tools as much as possible. Human expertise then comes into play when deep application knowledge is necessary (e.g., in rewriting queries and in overall hardware design) or when these tools do not work as advertised (the problems are all NP-hard).

Diagnosing performance problems and finding solutions may not require a good bedside manner, but good tuning can transform a slow and sick database into one full of pep.

9.8 Information

Whereas the remarks of this chapter apply to most database systems, each vendor will give you valuable specific information in the form of tuning guides or administrator's manuals. The guides vary in quality, but they are particularly useful for telling you how to monitor such aspects of your system as the relationship between buffer space and hit ratio, the number of deadlocks, the input/output load, and so on.

Our book *Database Tuning: Principles, Experiments, and Troubleshooting Techniques*, published by Morgan Kaufmann goes into greater depth regarding all the topics in this chapter. Our website http://www.databasetuning.org contains a repository of experiments and results obtained on current database systems.

Glossary

B-tree: The most used data structure in database systems. A B-tree is a balanced tree structure that permits fast access for a wide variety of queries. In virtually all database systems, the actual structure is a B+ tree in which all key–pointer pairs are at the leaves.

Clustering index: A data structure plus an implied table organization. For example, if there is a clustering index based on a B-tree on last name, then all records with the last names that are alphabetically close will be packed onto as few pages as possible.

Column-oriented store: In such a storage layout, tables are laid out column-wise, so all the employee ids are contiguous, all the salaries are contiguous, etc.

Conflict (between locks): An incompatibility relationship between two lock types. Read locks are compatible (nonconflicting) with read locks, meaning different transactions may have read locks on the same data item s. A write lock, however, conflicts with all kinds of locks.

Covering index: An index whose fields are sufficient to answer a query.

Data mining: The activity of finding actionable patterns in data.

Decision support: Queries that help planners decide what to do next, e.g., which products to push, which factories require overtime, and so on.

Denormalization: The activity of changing a schema to make certain relations denormalized for the purpose of improving performance (usually by reducing the number of joins). Should not be used for relations that change often or in cases where disk space is scarce.

Dense index: An index in which the underlying data structure has a pointer to each record among the data pages. Clustering indexes can be dense in some systems (e.g., ORACLE). Nonclustering indexes are always dense.

E-commerce applications: Applications entailing access to a website and a back end database system.

Hash structure: A tree structure whose root is a function, called the hash function. Given a key, the hash function returns a page that contains pointers to records holding that key or is the root of an overflow chain. Should be used when selective equality queries and updates are the dominant access patterns.

Heap: In the absence of a clustering index, the tuples of a table will be laid out in their order of insertion. Such a layout is called a heap. (Some systems, such as RDB, reuse the space in the interior of heaps, but most do not.)

Hit ratio: The number of logical accesses satisfied by the database buffer divided by the total number of logical accesses.

Index: A data organization to speed the execution of queries on tables or object-oriented collections. It consists of a data structure, e.g., a B-tree or hash structure, and a table organization.

Index organized table: A table clustered based on its primary key or on a row id if no primary key is defined.

Locking: The activity of obtaining and releasing read locks and write locks (see corresponding entries) for the purposes of concurrent synchronization (concurrency control) among transactions.

Nonclustering index: A dense index that puts no constraints on the table organization, also known as a secondary index. For contrast, see **clustering index**.

Normalized: A relation R is normalized if every functional dependency "X functionally determines A," where A and the attributes in X are contained in R (but A does not belong to X), has the property that X is the key or a superset of the key of R. X functionally determines A if any two tuples with the same X values have the same A value. X is a key if no two records have the same values on all attributes of X.

On-line transaction processing: The class of applications where the transactions are short, typically 10 disk I/Os or fewer per transaction, the queries are simple, typically point and multipoint queries, and the frequency of updates is high.

Read lock: If a transaction T holds a read lock on a data item x, then no other transaction can obtain a write lock on x.

Seek: Moving the read/write head of a disk to the proper track.

Serializability: The assurance that each transaction in a database system will appear to execute in isolation of all others. Equivalently, the assurance that a concurrent execution of committed transactions will appear to execute in serial order as far as their input/output behaviors are concerned.

Solid State Drive (SSD): A storage device that is composed of tens of flash chips connected to a micro-controller. The current generation of SSD exposes a block device interface similar to the magnetic hard drive interface. The micro-controller runs a firmware called flash translation layer (or FTL) that maps operations on logical block addresses onto operations on physical blocks on flash. SSDs can be directly installed on a server's memory bus (PCI bus), or they can be accessed as IO devices (via a SATA interface).

Sparse index: An index in which the underlying data structure contains exactly one pointer to each data page. Only clustering indexes can be sparse.

Track: A narrow ring on a single platter of a disk. If the disk head over a platter does not move, then a track will pass under that head in one rotation. The implication is that reading or writing a track does not take much more time than reading or writing a portion of a track.

Transaction: A program fragment delimited by Commit statements having database accesses that are supposed to appear as if they execute alone on the database. A typical transaction may process a purchase by increasing inventory and decreasing cash.

Two-phase locking: An algorithm for concurrency control whereby a transaction acquires a write lock on x before writing x and holds that lock until after its last write of x; acquires a read or write lock on x before reading x and holds that lock until after its last read of x; and never releases a lock on any item x before obtaining a lock on any (perhaps different) item y. Two-phase locking can encounter deadlock. The database system resolves this by rolling back one of the transactions involved in the deadlock.

Vertical partitioning: A method of dividing each record (or object) of a table (or collection of objects) so that some attributes, including a key, of the record (or object) are in one location and others are in another location, possibly another disk. For example, the account id and the current balance may be in one location and the account id and the address information of each tuple may be in another location.

Write lock: If a transaction T holds a write lock on a datum x, then no other transaction can obtain any lock on x.

10.1 Introduction

We are witnessing a tremendous growth in the size of the data gathered, stored, and processed by various kinds of information systems. Therefore, no matter how big memories become, there is always the need to store data in secondary or even tertiary storage to facilitate access. Even if the data set can fit in main memory, there is still a need to organize data to enable efficient processing. In this chapter, we discuss the most important issues related to the design of efficient access methods (i.e., indexing schemes), which are the fundamental tools in database systems for efficient query processing. For the rest of the discussion, we are going to use the terms access method and index interchangeably.

Take, for example, a large data set containing information about millions of astronomical objects (e.g., stars, planets, comets). An astronomer may require some information out of this data set. Therefore, the most natural way to proceed is to store the data set in a database management system (DBMS) in order to enjoy SQL-like query formulation. For example, a possible query in natural language is: "show me all stars which are at most 1000 light-years away from the sun." To answer such a query efficiently, one should avoid the exhaustive examination of the whole data set. Otherwise, the execution of each query will occupy the system for a long period of time, which is not practical and leads to performance degradation.

For the rest of the discussion, we are mainly interested in **disk-based access methods**, where the data set as well as the auxiliary data structures to facilitate access reside on magnetic disks. The challenge in this case is to perform as few **disk accesses** as possible, because each random access to the disk (i.e., reading or writing a block) costs about 5–8 ms, which is significantly slower than processing in main memory. Moreover, we assume that our data are represented by records of the form $<a_1; a_2,\ldots, a_m>$,

where each a_i denotes an attribute value. Attribute values may be simple, an integer for example, or may correspond to more complex objects such as points in 3D space or other geometric shapes. When needed, we are going to make clear the kind of data supported by each access method. For example, some access methods are good in organizing unidimensional objects (e.g., price, salary, population), whereas others have been specifically designed to handle points or rectangles in 2D or 3D space, text, DNA sequences, time-series, to name a few.

10.2 Underlying Principles

In contrast to memory-resident data structures, handling large data collections requires the corresponding access method (or at least a large part of it) to reside on secondary storage. Although flash memories are currently widely used, the magnetic disk continues to be the predominant secondary storage medium, used extensively by large information systems. The fundamental disk limitation is that accessing data on a disk is hundreds of times slower than accessing it in main memory. In fact, this limitation was the driving force underlying the development of efficient access methods trying to reduce the impact of this limitation as much as possible. In this section, we discuss briefly some key issues in access methods.

10.2.1 Blocks and Records

The fundamental characteristic of an access method is that the data are accessed in chunks called **pages** or **blocks**. In particular, whenever a data item x is requested, instead of fetching only x, the system reads a whole set of data items that are located near item x. In our context, near means within the same block. Each block can accommodate a number of data items. Usually, all blocks are of the same size B. Typical block sizes are 4 Kb, 8 Kb, 16 Kb, or larger. Obviously, the larger the block size, the more data items can fit in every block. Moreover, the number of items that fit in each block depends also on the size of each data item. One of the primary concerns in the design of efficient access methods is storing data items that are likely to be requested together in the same block (or nearby blocks). Thus, the target is to fetch into memory more useful data by issuing only one block access. Since this is not feasible in all cases, a more practical goal is to reduce the number of accesses (reads or writes) as much as possible.

There are two fundamental types of block accesses that are usually supported by access methods: a **random access** involves fetching a randomly selected block from the disk, whereas a **sequential access** just fetches the next block. Usually, a random access is more costly because of the way magnetic disks operate. To facilitate a random access, the **disk heads** must be positioned right on top of the track that contains the requested block, thus requiring a significant amount of time, called **seek time**. In fact, seek time is the predominant cost of an I/O disk operation. On the other hand, a sequential access just reads blocks one by one in a get-next fashion, thus requiring less seek time. However, to facilitate sequential access blocks must be located in nearby positions on the disk to minimize the required seek operations. In general, sequential access is more restrictive and easier to obtain than random access. In addition, random access is more useful because of the flexibility offered to access any block any time.

Next, we describe briefly how records are organized inside each block. We limit our discussion for the case where records are of **fixed size** denoted as R. Therefore, the maximum number of records that can fit in a block of size B is simply $\lfloor B/R \rfloor$. There are two basic alternatives we may follow to organize these records inside the block. The first approach is to force that all free space will be placed at the end of the block. This means that whenever we delete a record, its place will be taken by the last record in the block. The second alternative is to use a small index in the block header recording information about which record slot is occupied and which one is free. The second alternative avoids moving records inside the block, but reduces the capacity of the block because of the index used. In case **variable size** records are allowed, we expect that less storage will be required but processing time may increase due to some extra bookkeeping required to locate each record.

10.2.2 Fundamental Operations

Although access methods have different capabilities depending on their design and the problem they call to support, they all are primarily built to support a set of fundamental operations. The most significant one is **searching**. In the simplest case, a search operation takes as input a value and returns some information back to the caller. For example: "What is the perimeter of the Earth?," "Display the ids of the customers located in Greece," "What is the salary of John Smith?" or "Is Jack Sparrow one of our customers?" All these **queries** can be formulated as simple search operations. However, to support these queries as efficiently as possible, the corresponding access method should provide access to the appropriate record attributes. For example, to find the perimeter of the Earth, the access method must be searchable by the name of an astronomical object. Otherwise, the only way to spot the answer is to resort to sequential scanning of the whole data set. Similarly, to display the customers residing in Greece, our access method must be able to search by the name of the country.

There are other search-oriented queries that are clearly much more complex. For example, "find the names of the cities with a population at least 1 million and at most 5 millions." Clearly, this query involves searching in an interval of populations rather than focusing on a single population value. To support such a query efficiently, the access method must be equipped with the necessary tools. Note also, that depending on the application, searching may take other forms as well. For example, if the access method organizes points in the 2D space, then we may search by a region asking for all points falling in the region of interest. In any case, to facilitate efficient search, the access method must be organized in such a way that queries can be easily handled, avoiding scanning the whole database.

Two operations that change the contents of an access method are the insertion of new objects and the deletion of existing ones. If the access method does not support these operations, it is characterized as **static**; if both are supported, it is called **dynamic**; whereas if only insertions are supported, then it is called **semi-dynamic**. In the static case, the access method will be built once and there is no need to support insertions/deletions. The dynamic case is the most interesting and challenging one, since most of the real-life applications operate over data sets that change continuously, and potentially quite rapidly. Thus, insertions and deletions must be executed as fast as possible to allow for efficient maintenance of the access method.

In some cases, there is a need to build an access method when the corresponding data set is known in advance. The simplest solution is to just perform many invocations of the insertion operation. However, we can do much better because the data set is known, and therefore with appropriate preprocessing the index may be built much faster than by using the conservative one-by-one insertion approach. The operation of building the index taking into consideration the whole data set is called **bulk loading**.

10.3 Best Practices

In this section, we study some important indexing schemes that are widely used both in academia and industry. First, we discuss about the ***B*-tree** and **hashing** which are the predominant access methods for 1D indexing. Then, we center our focus to spatial access methods and discuss the ***R*-tree** and briefly some of its variations.

10.3.1 Fundamental Access Methods

The two dominant categories of fundamental external memory indexing methods are tree-based methods and hash-based methods. For tree-based methods, the dominant example is the B-tree [5], while for hash-based methods linear [38] and extendible [18] hashing are the most common ones. In the following, we briefly present both methods and their variants/extensions.

10.3.1.1 *B*-Tree

The *B*-tree [5] is a ubiquitous data structure when it comes to external memory indexing, and it is a generalization of balanced binary search trees. The intuition behind this generalization is that reading a block should provide the maximum information to guide the search. The use of binary trees may result in all nodes on a search path to reside in distinct blocks, which incurs an $O(\log_2 n)$ overhead while our goal is to impose that the number of blocks to read in order to find an element is $O(\log_B n)$ (i.e., logarithmic with respect to the data set cardinality). The *B*-tree with parameters k (corresponding to the internal node degree) and c (corresponding to leaf capacity) is defined as follows:

1. All internal nodes v have degree $d(v)$ such that $\ell \cdot k \leq d(v) \leq u \cdot k$, where $u > \ell > 0$. The only exception is the root, whose degree is lower-bounded by 2.
2. All leaves lie at the same level; that is, the depth of all leaves is equal.
3. All leaves l have size $|l|$ such that $\ell' \cdot c \leq |l| \leq c$, where $0 < \ell' < 1$.

The maximum height of the tree is $\lfloor \log_{\ell \cdot k}(n/\ell' c) + 1 \rfloor$ while its minimum height is $\lceil \log_{u \cdot k}(n/c) \rceil$. Depending on the satellite information of each element, the size of the pointers, as well as any other needed information within each block, we may set accordingly constants k, c, ℓ, ℓ', and u. Additionally, these parameters are also affected by the desired properties of the tree. Henceforth, for simplicity and without loss of generality, we assume that $k = c = B$, $u = 1$, and $\ell = \ell' = 1/2$.

In the classic *B*-tree, internal nodes may store elements (records) apart from pointers to children. This results in the decrease of parameter k and thus the height of the tree is increased. In practice, and to avoid this drawback, the B^+-trees [15] are extensively used. These trees store elements only at leaves while internal nodes store routing information related to the navigation during search within the tree. In this way, the parameter k is increased considerably and the height of the tree is reduced.

To perform a search for an element x, the search starts from the root and moves through children pointers to other internal nodes toward the leaves of the tree. When a leaf l is found, it is brought into main memory and a sequential or binary search is performed to find and return the element x or to report failure. One can also return the predecessor or the successor of the element x (which is x if it exists in the tree), but one more I/O may be needed. To support range search queries, the B^+-tree is usually changed so that all leaves constitute a linked list. As a result, for the range query $[x_1, x_2]$, first the leaf is located that contains the successor of x_1, and then a linear scan of all leaves whose value is within the range $[x_1, x_2]$ is performed with the help of the linked list of leaves. Before moving to update operations, we first briefly discuss the rebalancing operations. The B^+-tree (in fact all such trees) can be restored after an update operation by means of splits, fusions, and shares.

A node v is split when there is no available space within the node. In this case, half the information contained in v (pointers and routing information in internal nodes or elements at leaves) is transferred to a new node v' and thus both nodes have enough free space for future insertions. However, the father of v has its children increased by one, which means that there may be a cascading split possibly reaching even the root. A node v requires fusion with a sibling node v' when the used space within v is less than $\frac{1}{2}$B due to a deletion. In this case, if the combined size of v and v' is $>B$, then some information is carried over from v' to v. In this case we have a share operation which is a terminal rebalancing operation in the sense that the number of children of the father of v and v' remains the same. Otherwise, all information of v is transferred to v' and v is deleted. The father of v' has its children reduced by one and so there may be cascading fusions toward the root.

An insertion operation invokes a search for the proper leaf l in which the new element must be inserted to respect the sorted order of elements in the B^+-trees. If l has available space, then the new element is inserted and the insertion terminates. If it does not have available space, then the leaf is split into two leaves l and l' and the new element is inserted to either l or l', depending on its value. Then, based on whether the father of l and l' needs split, the process continuous until an internal node with free space is reached or until the root is split. A deletion operation is similar with the exception that it invokes a fusion operation for rebalancing. In Figure 10.1 an example of a B^+-tree is depicted.

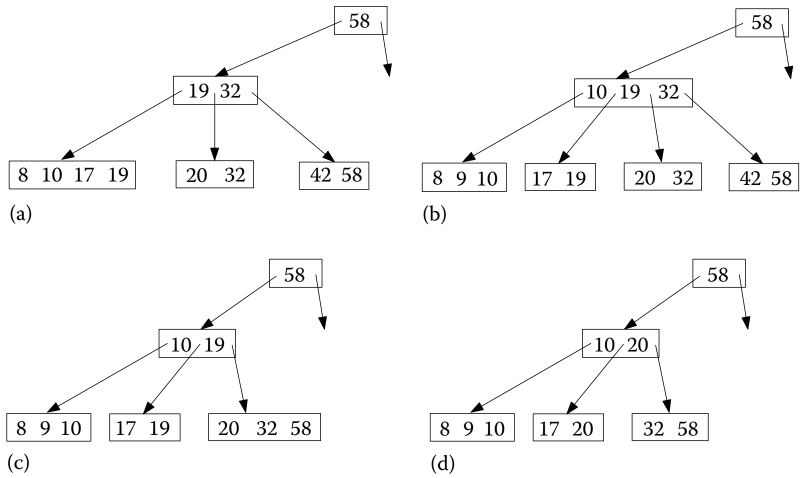

FIGURE 10.1 An example of update operations for the B^+-tree is depicted. Internal nodes contain only routing information. (a) An example of a B^+-tree ($B = 4$). (b) Adding 9 and performing a split. (c) Removing 42 and performing a fusion. (d) Removing 19 and performing a share.

A variant of the B^+-tree is the B^*-tree [15], which balances adjacent internal nodes to keep them more densely packed. This variant requires that $l = l' = \frac{2}{3}$ instead of $\frac{1}{2}$. To maintain this, instead of immediately splitting up a node when it gets full, its elements are shared with an adjacent node. As soon as the adjacent node gets full, then the two nodes are split into three nodes.

In total, search and update operations can be carried out in $O(\log_B n)$ I/Os while a range search query can be carried out in $O(\log_B n + (t/B))$ I/Os, where t is the number of reported elements.

10.3.1.2 *B*-Tree Variations and Extensions

There are numerous variants and extensions of B-trees, and we only report some of them. Most of these, if not all, are quite complicated to implement and can be used in practice only in particular scenarios. The Lazy B-tree [33] support updates with $O(1)$ worst-case rebalancings (not counting the search cost) by carefully scheduling these operations over the tree. The ISB-tree [33] uses interpolation search in order to achieve a $O(\log_B \log n)$ expected I/Os for searching and updating, provided that the distribution of the elements belongs to a large family of distributions with particular properties. It is simple to extend basic B^+-trees to maintain a pointer to the parent of each node as well as to maintain that all nodes at each level are connected in a doubly linked list. Applying these changes, the B^+-tree can support efficiently finger searches [11] such that the number of I/Os for searching becomes $O(log_B d)$, where d is the number of leaves between a leaf l designated as the finger and the leaf l' we are searching for. When searching for nearby leaves, this is a significant improvement over searching for l' from the root. One can also combine B-trees with hashing [43] to speed-up operations.

There are numerous extensions of B-trees that provide additional functionalities and properties. The weight-balanced B-tree [4] has the weight property that normal B-trees lack. For an internal node v let $w(v)$ be its weight, which is the number of elements stored in the subtree of v. The weight property states that an internal node v is rebalanced only after $\Theta(w(v))$ updates have been performed at its subtree since the last update. This property is very important to reduce complexities when the B-tree has secondary structures attached to internal nodes [4]. A partial persistent B-tree [7] is a B-tree that maintains its history attaining the same complexities with normal B-trees. Efficient fully persistent B-trees have very recently been designed [12] and allow updates in the past instances of the B-tree giving rise to different history paths. String B-trees [19] have been designed to support efficiently search and update operations

on a set of strings (and its suffixes) in external memory. Cache-oblivious B-trees [9] have been designed that do not need to know basic parameters of the memory hierarchy (like B) in order to attain the same complexities as normal B-trees, which make heavy use of the knowledge of these parameters. Finally, buffer trees [3] are B-trees that allow for efficient execution of batch updates (or queries). This is accomplished by lazily flushing toward the leaves all updates (or queries) in the batch. In this way, each update can be supported in $O((1/B)\log_{M/B}(n/B))$ I/Os.

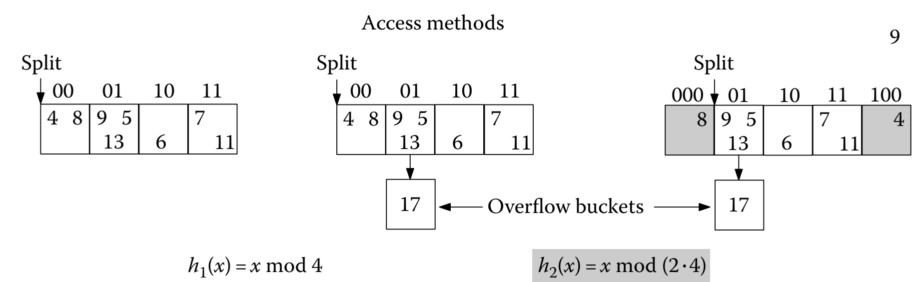
10.3.1.3 Hashing

Another much used technique for indexing is hashing. Hashing is faster than B-trees by sacrificing in functionality. The functionality of hashing is limited when compared to B-trees because elements are stored unsorted and thus there is no way to support range queries or find the successor/predecessor of an element. In hashing, the basic idea is to map each object to a number corresponding to the location inside an array by means of a hash function. It is not our intention to describe hash functions and thus we refer the interested reader to [16] and the references therein for more information on practical hash functions.

The largest problem with hashing is collision resolution, which happens when two different elements hash to the same location. The hash function hashes elements within buckets, which in this case is a block. When the bucket becomes full, then either a new overflow bucket is introduced for the same hashed value or a rehashing is performed. All buckets without the overflowing buckets constitute the primary area. Two well-known techniques are **linear hashing** [38] and **extendible hashing** [18]. The first method extends the hash-table by one when the fill factor of the hash-table (the number of elements divided by the size of the primary area) goes over a critical value. The second one extends the primary area as soon as an overflowing bucket is about to be constructed.

In linear hashing, data are placed in a bucket according to the last k bits or the last $k + 1$ bits of the hash function value of the element. A pointer *split* keeps track of this boundary. The insertion of a new element may cause the fill factor to go over the critical value, in which case the bucket on the boundary corresponding to k bits is split into two buckets corresponding to $k + 1$ bits. The number of buckets with k bits is decreased by one. When all buckets correspond to $k + 1$ bits, another expansion is initiated constructing new buckets with $k + 2$ bits. Note that there is no relationship between the bucket in which the insertion is performed and the bucket that is being split. In addition, linear hashing uses overflow buckets although it is expected that these buckets will be just a few. The time complexity for a search and update is $O(1)$ expected. In Figure 10.2 an example of an insertion is depicted.

On the other hand, extendible hashing does not make use of overflow buckets. It uses a directory that may index up to 2^d buckets, where d, the number of bits, is chosen so that at most B elements exist in each bucket. A bucket may be pointed by many such pointers from the directory since they may be indexed



(a) Fill factor $\frac{8}{12} < 0.7$ (b) Insert 17, fill factor $\frac{9}{12} > 0.7$ (c) Fill factor $\frac{9}{15} < 0.7$

FIGURE 10.2 Assuming that the critical fill factor is 0.7, then when 17 is inserted in (a), an overflow bucket is introduced (b) since the bucket corresponding to bits 01 has no space. After the insertion, the fill factor is >0.7 and as such we construct a new hash function $h_2(x)$ and introduce a new bucket (c). $h_2(x)$ is applied to gray buckets (3 bits) while $h_1(x)$ is applied to white buckets (2 bits) only.

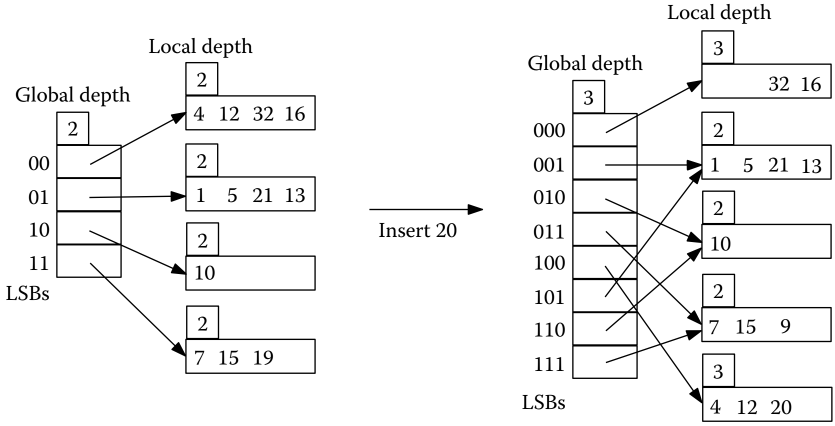


FIGURE 10.3 An example of re-organization for extendible hashing. After the insertion of 20 the first bucket overflows and we construct a new table of global depth 3; that is, with 2^3 entries. Only the overflowing bucket is split and has local depth 3, thus needing 3 bits to navigate. The buckets that did not overflow need only 2 bits and thus 2 pointers point to them.

by using less than d bits. An insertion either causes the directory to double or some of entries of the directory are changed. For example, a bucket pointed by eight entries will be split and both new buckets are pointed by four entries. In case a bucket is pointed only by one entry and needs to be split, then the directory needs to be doubled. The advantage of extendible hashing is that it never has more than two disk accesses for any record since there are no overflow buckets to traverse. The main problems with this variation on hashing are total space utilization and the need for massive reorganization (of the table). In Figure 10.3, an example of such a reorganization for an insertion is depicted.

There are many other hashing schemes with their own advantages and disadvantages. Cuckoo hashing [45] is one such scheme which is very promising because of its simplicity. The basic idea is to use two hash functions instead of only one and thus provide two possible locations in the hash-table for each element. When a new element is inserted, it is stored in one of the two possible locations provided by the hash functions. If both of these locations are not empty, then one of them is kicked out. This new displaced element is put into its alternative position and the process continues until a vacant position has been found or until many such repetitions have been performed. In the last case, the table is rebuilt with new hash functions. Searching for an element requires inspection of just two locations in the hash-table, which takes constant time in the worst case.

10.3.2 Spatial Access Methods

The indexing schemes discussed previously support only one dimension. However, in applications such as Geographic Information Systems (GIS), objects are associated with spatial information (e.g., latitude/longitude coordinates). In such a case, it is important to organize the data taking into consideration the spatial information. Although there are numerous proposals to handle spatial objects, in this chapter we will focus on the *R*-tree index [24], which is one of the most successful and influential spatial access methods, invented to organize large collections of rectangles for VLSI design.

10.3.2.1 *R*-Tree

R-trees are hierarchical access methods based on B^+-trees. They are used for the dynamic organization of a set of d-dimensional geometric objects representing them by the minimum bounding d-dimensional rectangles (for simplicity, MBRs in the sequel). Each node of the *R*-tree corresponds to the MBR that bounds its children. The leaves of the tree contain pointers to the database objects instead of pointers

to children nodes. The nodes are implemented as disk blocks. It must be noted that the MBRs that surround different nodes may overlap each other. Besides, an MBR can be included (in the geometrical sense) in many nodes, but it can be associated to only one of them. This means that a spatial search may visit many nodes before confirming the existence of a given MBR. An *R*-tree of order (m, M) has the following characteristics:

- Each leaf node (unless it is the root) can host up to M entries, whereas the minimum allowed number of entries is $m \leq \mathrm{M}/2$. Each entry is of the form (*mbr, oid*), such that *mbr* is the MBR that spatially contains the object and *oid* is the object's identifier.
- The number of entries that each internal node can store is again between $m \leq \mathrm{M}/2$ and M. Each entry is of the form (*mbr, p*), where p is a pointer to a child of the node and *mbr* is the MBR that spatially contains the MBRs contained in this child.
- The minimum allowed number of entries in the root node is 2.
- All leaves of the *R*-tree are located at the same level.

An *R*-tree example is shown in Figure 10.4 for the set of objects shown on the left. It is evident that MBRs R_1 and R_2 are disjoint, whereas R_3 has an overlap with both R_1 and R_2. In this example we have assumed that each node can accommodate at most three entries. In a real implementation, the capacity of each node is determined by the block size and the size of each entry which is directly related to the number of dimensions.

The *R*-tree has been designed for dynamic data sets and, therefore, it supports insertions and deletions. To insert a new object's MBR, the tree is traversed top-down, and at each node a decision is made to select a branch to follow next. This is repeated until we reach the leaf level. The decision we make at each node is based on the criterion of area enlargement. This means that the new MBR is assigned to the entry which requires the least area enlargement to accommodate it. Other variations of the *R*-tree, such as the R^*-tree [8], use different criteria to select the most convenient path from the root to the leaf level. Upon reaching a leaf L, the new MBR is inserted, if L can accommodate it (there is at least one available slot). Otherwise, there is a node overflow and a **node split** occurs, meaning that a new node L' is reserved. Then, the old entries of L (including the new entry) are distributed to two nodes L and L'. Note that a split at a leaf may cause consecutive splits in the upper levels. If there is a split at the root, then the height of the tree increases by one.

The split operation must be executed carefully to maintain the good properties of the tree. The primary concern while splitting is to keep the overlap between the two nodes as low as possible. This is because the higher the overlap, the larger the number of nodes that will be accessed during a search operation. In the original *R*-tree proposal, three split policies have been studied, namely, exponential, quadratic, and linear.

Exponential split: All possible groupings are exhaustively tested and the best one, with respect to the minimization of the MBR enlargement, is chosen.

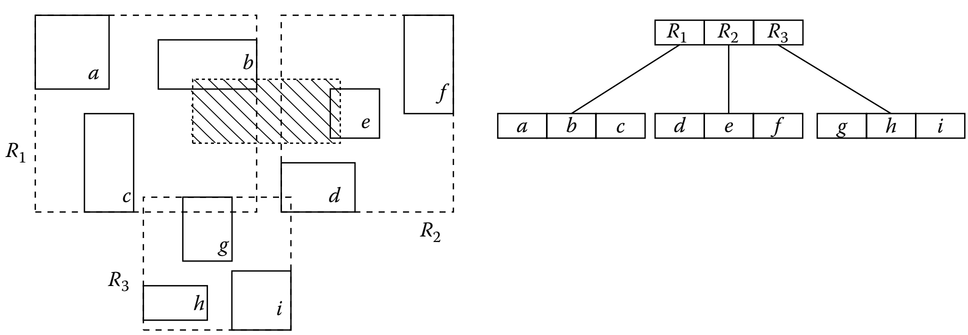

FIGURE 10.4 *R*-tree example.

Algorithm RANGESEARCH (**Node** *N*, **Region** *Q*)
Input: root mode *N*, query region *Q*
Output: answer set *A*

```
1.  if (N is not a leaf node)
2.      examine each entry E of N to find those E.mbr that intersect Q
3.      foreach such entry E call RangeSearch(E.ptr,Q)
4.  else // N is a leaf node
5.      examine all entries E and find those for which E.mbr intersects Q
6.      add these entries to the answer set A
7.  Endif
```

FIGURE 10.5 The *R*-tree range search algorithm.

Quadratic split: Choose two objects as seeds for the two nodes, where these objects if put together create as much empty space as possible. Then, until there are no remaining objects, insert the object for which the difference of dead space if assigned to each of the two nodes is maximized in the node that requires less enlargement of its respective MBR.

Linear split: Choose two objects as seeds for the two nodes, where these objects are as far apart as possible. Then, consider each remaining object in a random order and assign it to the node requiring the smallest enlargement of its respective MBR.

The quadratic split policy is the best choice that balances efficiency and effectiveness and, therefore, it is widely used in *R*-tree implementations.

In a deletion, an entry is removed from the leaf level of the tree, which may cause a node underflow. In this case, **re-insertion** of entries is applied to reduce the space requirements of the tree. In general, a deletion has the opposite effect than that of an insertion. In both cases, the path from the root to the leaf level that was affected by the operation must be adjusted properly to reflect the changes performed in the tree. Thus, the deletion of an entry may cause a series of deletions that propagate up to the root of the *R*-tree. If the root has only one child, then it is removed and the height of the tree decreases by one.

In the sequel, we examine briefly how search is performed in an *R*-tree. We will center our focus to range queries, where the user defines a query region *Q* and the answer to the query contains the spatial objects that intersect *Q*. For example, in Figure 10.4, the query region is shown filled, whereas the answer to the query is composed of the objects *b* and *e*. The outline of the algorithm that processes range queries in an *R*-tree is given in Figure 10.5. For a node entry *E, E.mbr* denotes the corresponding MBR and *E.p* the corresponding pointer to the next level. If the node is a leaf, then *E.p* denotes the corresponding object identifier (*oid*). We note that the rectangles that are found by range searching constitute the candidates of the filtering step. The actual geometric objects intersected by the query rectangle have to be found in a refinement step by retrieving the objects of the candidate rectangles and testing their intersection.

10.3.2.2 R-Tree Bulk Loading

Recall that bulk loading is the process of building an index by taking into consideration the data set which is known in advance. Thus, usually this operation is applied for static data sets or when insertions and deletions are rare. In most of the cases, when bulk loading is applied, the leaf level of the tree is created first. Then, the upper tree levels can be built one by one until we reach the root.

The first bulk-loading algorithm for *R*-trees proposed in [47] first sorts the data objects by using the x coordinate of their center. If objects are points rather than rectangles, then the x coordinate of the point is used. By using the sorted order, the leaves may be formed by placing the first M entries in the first leaf, until no more data are available. This way, all leaves will be 100% full, except maybe of the last leaf which may contain less.

Another contribution to this problem is reported in [30]. The algorithm is similar to that of [47] in that again a sorting is performed in order to build the leaf level of the tree. Sorting is performed by using the Hilbert value of the data objects' centroids. According to the performance evaluation given in [30], this approach shows the best overall performance with respect to the cost of performing queries.

STR (Sort-Tile-Recursive) is a bulk-loading algorithm for *R*-trees proposed by Leutenegger et al. [32]. Let *n* be a number of rectangles in 2D space. The basic idea of the method is to tile the address space by using *V* vertical slices, so that each slice contains enough rectangles to create approximately $\sqrt{n/M}$ nodes, where *M* is the *R*-tree node capacity. Initially, the number of leaf nodes is determined, which is $L = \lceil n/M \rceil$. Let $V = \sqrt{L}$. The rectangles are sorted with respect to the *x*-coordinate of the centroids, and *V* slices are created. Each slice contains *V.M* rectangles, which are consecutive in the sorted list. In each slice, the objects are sorted by the *y*-coordinate of the centroids and are packed into nodes (placing *M* objects in a node). Experimental evaluation performed in [32] has demonstrated that the STR method is generally better than previously proposed bulk-loading methods. However, in some cases the Hilbert packing approach performs marginally better.

10.3.2.3 R-Tree Variations and Extensions

Several *R*-tree variations have been proposed in the literature to improve the performance of queries. Here we discuss briefly three successful variations that show better performance than the original proposal by Guttman. These variations differ in several aspects like the way insertions and deletions are performed, the optimization criteria being used, the split policy applied, and the storage utilization.

The R^+-tree: R^+-trees were proposed as an alternative that avoids visiting multiple paths during point location queries, aiming at the improvement of query performance [52]. Moreover, MBR overlapping of internal modes is avoided. This is achieved by using the clipping technique. In other words, R^+-trees do not allow overlapping of MBRs at the same tree level. In turn, to achieve this, inserted objects have to be divided in two or more MBRs, which means that a specific object's entries may be duplicated and redundantly stored in several nodes. Therefore, a potential limitation of R^+-trees is the increased space requirements due to redundancy.

The R^*-tree: R^*-trees [8] were proposed in 1990 but are still very well received and widely accepted in the literature as a prevailing performance-wise structure that is often used as a basis for performance comparisons. As already discussed, the *R*-tree is based solely on the area minimization of each MBR. On the other hand, the R^*-tree goes beyond this criterion and examines the following: (1) minimization of the area covered by each MBR, (2) minimization of the overlap between MBRs, (3) minimization of MBR margins (perimeters), and (4) maximization of storage utilization. The R^*-tree follows an engineering approach to and the best possible combinations of the aforementioned criteria. This approach is necessary, because the criteria can become contradictory. For instance, to keep both the area and the overlap low, the lower allowed number of entries within a node can be reduced. Therefore, storage utilization may be impacted. Also, by minimizing the margins so as to have more quadratic shapes, the node overlapping may be increased.

The Hilbert R-tree: The Hilbert *R*-tree [31] is a hybrid structure based on the *R*-tree and the B^+-tree. Actually, it is a B^+-tree with geometrical objects being characterized by the Hilbert value of their centroid. The structure is based on the Hilbert space-filling curve. It has been shown in [42] that the Hilbert space-filling curve preserves well the proximity of spatial objects. Entries of internal tree nodes are augmented by the largest Hilbert value of their descendants. Therefore, an entry *e* of an internal node is a triple of the form $< mbr, H, p >$ where *mbr* is the MBR that encloses all the objects in the corresponding subtree, *H* is the maximum Hilbert value of the subtree, and *p* is the pointer to the next level. Entries in leaf nodes are exactly the same as in *R*-trees, R^+-trees, and R^*-trees and are of the form $< mbr, oid >$, where *mbr* is the MBR of the object and *oid* the corresponding object identifier.

10.3.3 Managing Time-Evolving Data

Time information plays a significant role in many applications. There are cases where in addition to the data items per se, the access method must maintain information regarding the time instance that a particular event occurred. For example, if one would like to extract statistical information regarding the sales of a particular product during the past 5 years, the database must maintain historical information. As another example, consider an application that tracks the motion patterns of a specific species. To facilitate this, each location must be associated with a timestamp. Thus, by inspecting the location in consecutive timestamps, one may reveal the motion pattern of the species. For the rest of the discussion, we assume that time is discrete and each timestamp corresponds to a different time instance.

One of the first access methods that was extended to support time information is the *B*-tree and its variations. The most important extensions are the following:

The time-split B-tree [39]: This structure is based on the write-once *B*-tree access method proposed in [17], and it is used for storing **multi-version data** on both optical and magnetic disks. The only operations allowed are insertions and searches, whereas deletions are not supported. The lack of deletions in conjunction with the use of two types of node splits (normal and time-based) is the main reason for the structure's space and time efficiency. However, only exact-match queries are supported efficiently.

The fully persistent B^+-tree [36]: In contrast to the time-split *B*-tree, the fully persistent B^+-tree supports deletions in addition to insertions and searches. Each record is augmented by two fields t_{start} and t_{end}, where t_{start} is the timestamp of the insertion and t_{end} is the timestamp when the record has been deleted, updated, or copied to another node. This way, the whole history can be recorded and queries may involve the past or the present status of the structure.

The multi-version B-tree [6]: This access method is asymptotically optimal and allows insertions and deletions only at the last (current) timestamp, whereas exact-match and range queries may be issued for the past as well. The methodology proposed in [6] may be used for other access methods, when there is a need to transform a simple access method to a multi-version one.

There are also significant research contributions in providing time-aware spatial access methods. An index that supported space and time is known as **spatiotemporal** access method. Spatiotemporal data are characterized by changes in location or shape with respect to time. Supporting time increases the number of query types that can be posed by users. A user may focus on a specific time instance or may be interested in a time interval. Spatiotemporal queries that focus on a single time instance are termed **time-slice queries**, whereas if they focus on a time interval, they are termed **time interval queries**. If we combine these choices with spatial predicates and the ability to query the past, the present, or the future, spatiotemporal queries can be very complex, and significant effort is required to process them.

A large number of the proposed spatiotemporal access methods are based on the well-known *R*-tree structure. In the following, we discuss briefly some of them.

The 3D R-tree [54]: In this index, time is considered as just another dimension. Therefore, a rectangle in 2D becomes a box in 3D. The 3D *R*-tree approach assumes that both ends of the interval $[t_{start}, t_{end})$ of each rectangle are known and fixed. If the end time t_{end} is not known, this approach does not work well, due to the use of large MBRs leading to performance degradation with respect to queries. In addition, conceptually, time has special characteristic, i.e., it increases monotonically. This suggests the use of more specialized access methods.

The partially persistent R-tree [34]: This index is based on the concept of partial persistency [35]. It is assumed that in spatiotemporal applications, updates arrive in time order. Moreover, updates can be performed only on the last recorded instance of the database, in contrast to general bitemporal data. The partially persistent *R*-tree is a directed acyclic graph of nodes with a number of root nodes, where each root is responsible for recording a subsequent part of the ephemeral *R*-tree evolution. Object records are

stored in the leaf nodes of the PPR-tree and maintain the evolution of the ephemeral *R*-tree data objects. As in the case of the fully persistent B^+-tree, each data record is augmented to include the two lifetime fields, t_{start} and t_{end}. The same applies to internal tree nodes, which maintain the evolution of the corresponding directory entries.

The multi-version 3D R-tree [53]: This structure has been designed to overcome the shortcomings of previously proposed techniques. It consists of two parts: a multi-version *R*-tree and an auxiliary 3D *R*-tree built on the leaves of the former. The multi-version *R*-tree is an extension of the multi-version *B*-tree proposed by Becker et al. [6]. The intuition behind the proposed access method is that time-slice queries can be directed to the multi-version *R*-tree, whereas time-interval queries can be handled by the 3D *R*-tree.

10.4 Advanced Topics

In this section, we discuss some advanced topics related to indexing. In particular, we focus on three important and challenging issues that attract research interest mainly due to their direct impact on performance and because they radically change the way that typical indexing schemes work. Namely, these topics are (1) cache-oblivious indexing, (2) on-line indexing, and (3) adaptive indexing.

10.4.1 Cache-Oblivious Access Methods and Algorithms

In 1999, Frigo et al. [20] introduced a new model for designing and analyzing algorithms and data structures taking into account memory hierarchies. This is the **cache-oblivious model** which, as its name implies, is oblivious to the parameters as well to some architectural characteristics of the memory hierarchy. Data structures designed in this model do not know anything about the memory hierarchy, but have performance which is comparable to data structures that have been designed with knowledge of the particular memory hierarchy. In a nutshell, this is accomplished by laying out the data structure over an array which is cache-oblivious by default. The main problem is how to design this layout and how to maintain it when it is subjected to update operations. The main advantage of these indexing schemes (an example is the cache oblivious *B*-tree [9]) is not only their simplicity and portability among different platforms but also their innate ability to work optimally in all levels of the memory hierarchy.

10.4.2 On-Line and Adaptive Indexing

Traditional physical indexing building follows an off-line approach to analyzing workload and creating the data structures to enable efficient query processing. More specifically, typically, a sample workload is analyzed with a view to selecting the indices to be built with the help of auto-tuning tools (e.g., [2,14,56]). This is an expensive process, especially for very large databases. On-line and adaptive indexing have introduced a paradigm shift, where indices are created on the y during query processing. In this way, database systems avoid a complex and time-consuming process, during which there is no index support, and can adapt to dynamic workloads. We draw a distinction between on-line and adaptive indexing following the spirit of [28]. According to that distinction, on-line indexing monitors the workload and creates (or drops) indices on-line during query execution (e.g., [13,40]). Adaptive indexing takes one step further: in adaptive indexing the process of index building is blended with query execution through extensions to the logic of the operators in the query execution plan (e.g., [23,25]). In the sequel, we discuss briefly these two approaches which differ significantly from the typical bulk-loading process for index building.

On-line Indexing: The paradigm of on-line indexing solutions departs from traditional schemes in that the index tuning mechanism is always running. A notable example of such category is described in [13], where the query engine is extended with capabilities to capture and analyze evidence information about the potential usefulness of indices that have not been created thus far. Another interesting approach is

soft-indices [40], which build on top of an index-tuning mechanism that continuously collects statistical information and periodically solves the NP-hard problem of index selection. Similarly to adaptive indexing, the new decisions are enforced during query processing but without affecting the operator implementation.

Adaptive Indexing: The most representative form of adaptive indexing is **database cracking** [25], which is mostly tailored to (in-memory) column-stores [1]. Database cracking revolves around the concept of continuous physical re-organization taking place at runtime. Such physical re-organization is automated, in the sense that does not involve human involvement, does not contain any off-line preparatory phase, and may not build full indices. The latter means that the technique is not only adaptive but also relies on partial indexing that is refined during workload execution in an incremental manner. To give an example, suppose that a user submits a range query on the attribute *R.A* for the first time and the range predicate is $value1 < R.\ A < value2$. According to database cracking, during execution, a copy of *R. A* will be created, called the *cracker column* of *R. A*. The data in that cracker column is physically re-organized and is split in three parts: (1)$value1 \leq R.\ A$; (2) $value1 < R.\ A < value2$; and (3) $R.\ A \leq$ value2. Moreover, an AVL tree, called *cracker index*, is created to maintain the partitioning information. This process of physical re-organization continues with every query. Overall, each query may benefit from the cracking imposed by previous queries and the new splits introduced may be of benefit for subsequent queries. In other words, the access methods are created on the y and are query-driven, so that they eventually match the workload. Database cracking is characterized by low initialization overhead, is continuously refined, and may well outperform techniques that build full indices, because the latter need a very large number of queries in order to amortize the cost of full index building to be outweighed. Cracking can be extended to support updates [26] and complex queries [27].

Nevertheless, database cracking may converge slowly and is sensitive to query pattern. Such limitations are mitigated by combining traditional indexing techniques (*B*-trees) with database cracking, resulting in the so-called adaptive merging [23]. The key distinction between the two approaches is that adaptive merging relies on merging rather than on partitioning, and that adaptive merging is applicable to disk-based data as well.

10.5 Research Issues

The field of access methods continues to be one of the most important topics in database management systems, mainly because of its direct impact on query performance. Although the field has been active for several decades, modern applications pose novel challenges that must be addressed carefully toward efficient processing. Here, we discuss briefly some of these challenges.

High-dimensional data: One of the most important challenges emerges when the number of attributes (dimensions) increases significantly. *R*-trees and related indexing schemes perform quite well for dimensionalities up to 15 or 20. Above this level, the dimensionality curse renders indexing difficult mainly due to concentration of measure effect. Unfortunately, the cases where high dimensionalities appear are not few. For example, in multimedia data management, images are often represented by feature vectors, each containing hundreds of attributes. There are several proposals in the literature to improve performance in these cases, trying to reduce the effects of dimensionality curse. For example, the X-tree access method proposed in [10] introduces the concept of **supernode** and avoids node splits if these cannot lead to a good partitioning. As another example, Vector Approximation File [55] is an approximation method that introduces error in query processing. For static data sets, dimensionality reduction may also be applied to first decrease the number of dimensions in order to be easier for access methods to organize the data.

Modern hardware: Hardware is evolving, and although the magnetic disk is still the prevailing secondary storage medium, new types of media have been introduced, such as **solid-state drives**.

Also, processors enjoy a dramatic change by the ability to include multiple cores in the same chip. These changes in hardware bring the necessity to change the way we access and organize the data. For example, solid-state drives do not suffer from the seek time problem and, therefore, the impact of I/O time on the performance becomes less significant. This means that operations that are I/O-bounded with magnetic disks may become CPU-bounded with modern hardware, due to the reduction in I/O time. The indexing problem becomes even more challenging as new processing and storage components like GPUs and FPGAs are being used more often. The new access methods must take into account the specific features of new technology.

Parallelism and distribution: The simultaneous use of multiple instances of resources such as memory, CPU, and disks brings a certain level of flexibility to query processing, but it also creates significant challenges in terms of overall efficiency. By enabling concurrent execution of tasks, we are facing the problem of coordinating these tasks and also the problem of determining where data reside. Therefore, parallel and distributed access methods are needed that are able to scale well with the number of processors. In addition to scalability, these techniques must avoid bottlenecks. For example, if we simply take an access method and place each block to a different processor, the processor that hosts the root will become a hot spot. Although there are many significant contributions for parallel/distributed indexing (e.g., distributed hash-tables), modern programming environments such as MapReduce on clusters or multi-core CPUs and GPUs call for a reconsideration of some concepts to enable the maximum possible performance gains and scalability.

On-line and adaptive indexing: On-line and adaptive indexing are technology in evolution; thus multiple aspects require further investigation. Among the most important ones, we highlight the need of investigation of concurrency control in database cracking techniques, the most fruitful combination of off-line, on-line, and adaptive techniques, and the application of database cracking to row stores. Finally, as new indexing methodologies are being proposed, we need a comprehensive benchmark in order to assess the benefits and weaknesses of each approach; a promising first step toward this direction is the work in [29].

10.6 Summary

Access methods are necessary toward efficient query processing. The success of an access method is characterized by its ability to organize data in such a way that locality of references is enhanced. This means that data that are located in the same block are likely to be requested together. In this chapter, we discussed some fundamental access methods that enjoy a wide-spread use by the community due to their simplicity and their excellent performance. Initially, we discussed some important features of access methods and then we described *B*-trees and hashing which are the prevailing indexing schemes for 1D data and *R*-trees, which is the most successful family for indexing spatial and other types of multidimensional data. For *R*-trees we also described briefly bulk-loading techniques, which is an important operation for index creation when the data set is available. Finally, we touched the issues of on-line and adaptive indexing, which enjoy a growing interest due to the ability to adapt dynamically based on query workloads. Access methods will continue to be a fundamental research topic in data management. In the era of big data, there is a consistent need for fast data management and retrieval, and thus indexing schemes are the most important tools in this direction.

Glossary

***B*-tree:** A tree-based index that allows queries, insertions, and deletions in logarithmic time.
Bulk loading: The insertion of a known before-hand sequence of objects into a set of objects.
Cache-oblivious model: A model that supports the design of algorithms and data structures for memory hierarchies without knowing its defining parameters.

Cuckoo hashing: Hashing that uses two hash functions to guarantee worst-case $O(1)$ accesses per search.
Database cracking: A form of continuous physical re-organization taking place at runtime.
Disk access: Reading (writing) a block from (to) the disk.
Disk-based access method: An access method that is designed specifically to support access for disk-resident data.
Disk head: The electronic component of the disk responsible for reading and writing data from and to the magnetic surface.
Dynamic access method: An access method that allows insertions, deletions, and updates in the stored data set.
Extendible hashing: A hashing method that doubles the index size to avoid overflowing.
Fixed-size record: A record with a predetermined length which never changes.
Hashing: An index method that uses address arithmetic to locate elements.
Linear hashing: A hashing method that extends the main index by one each time the fill factor is surpassed.
Multi-version data: Data augmented by information about the time of their insertion, deletion, or update.
Node split: The operation that takes place when a node overflows, i.e., there is no room to accommodate a new entry.
On-line indexing: An indexing scheme where the index tuning mechanism is always running.
***R*-tree:** A hierarchical access method that manages multidimensional objects.
Random access: The operation of fetching into main memory a randomly selected block from disk or other media.
Re-insertion: The operation of re-inserting some elements in a block. Elements are first removed from the block and then inserted again in the usual manner.
Semi-dynamic access method: An access method that supports queries and insertions of new items; it does not support deletions.
Seek time: Time required for the disk heads to move to the appropriate track.
Solid-state drive: A data storage device that uses integrated circuits solely to store data persistently.
Spatiotemporal data: Data containing both spatial and temporal information.
Static access method: An access method that does not support insertions, deletions, and updates.
Supernode: A tree node with a capacity which is a multiple of the capacity of a regular node.
Time-slice query: A query posed on a specific timestamp.
Time-interval query: A query that refers to a time interval defined by two timestamps.
Variable-size record: A record whose length may change due to to changes in the size of individual attributes.

Further Information

There is a plethora of resources that the interested reader may consult to grasp a better understanding of the topic. Since access methods are related to physical database design, the book of Lightstone et al. [37] may be of interest to the reader. For a thorough discussion of *B*-trees and related issues, we recommend the article of Graefe in [22]. Also, almost every database-oriented textbook contains one or more chapters devoted to indexing. For example, Chapters 8–11 of [46] cover indexing issues in detail, in particular *B*-trees and hashing, in a very nice way.

For a detailed discussion of spatial access methods, the reader is referred to two books from Samet, [50] and [51]. In [50] the reader will find an in-depth examination of indexing schemes that are based on space portioning (e.g., linear quadtrees). Also, in [51], in addition to the very detailed study of spatial access methods, the author presents metric access methods, where objects reside in a metric space rather than in a vector space. For a thorough discussion of the *R*-tree family, the reader is referred to the book

of Manolopoulos et al. [41]. We also mention a useful survey paper of Gaede and Günther [21], which covers indexing schemes that organize multidimensional data.

In many applications, time information is considered very important and thus it should be recorded. For example, in a fleet management application, we must know the location of each vehicle and the associated timestamp. There are many approaches to incorporate time information into an index. Some of them were briefly discussed in Section 10.3.3. The reader who wants to cover this issue more thoroughly may consult other more specialized resources such as the survey of Salzberg and Tsotras [49] as well as the article of Nguyen-Dinh et al. [44]. In addition to the indexing schemes designed to support historical queries, some access methods support future queries. Obviously, to answer a query involving the near future, some information about the velocities of moving objects is required. The paper by Šaltenis et al. [48] describes such an index.

The previous resources cover more or less established techniques. For modern research issues in the area, the best sources are the proceedings of leading database conferences and journals. In particular, the proceedings of the major database conferences *ACM SIGMOD/PODS*, *VLDB*, *IEEE ICDE*, *EDBT/ICDT*, *ACM CIKM*, and *SSDBM* contain many papers related to access methods and indexing. Also, we recommend the journals *ACM Transactions on Database Systems*, *IEEE Transactions on Knowledge and Data Engineering*, *The VLDB Journal*, and *Information Systems* where, in most cases, the published articles are enhanced versions of the corresponding conference papers.

Query Optimization

Nicolas Bruno
Microsoft Corporation

11.1 Introduction

Database management systems, or DBMSs for short, let users specify queries using high-level declarative languages such as `SQL`. In such languages, we write *what* we want but not *how* to obtain the desired results. The latter task is delegated to the *query optimizer*, a component in the DBMS responsible for finding an efficient execution plan to evaluate the input query. The query optimizer searches a large space of alternatives and chooses the one that is expected to be least expensive to evaluate. Query optimization is absolutely necessary in a DBMS because the difference in runtime among alternatives and thus the overhead of a bad choice can be arbitrarily large. In fact, for queries of medium complexity, execution plans producing the same result can run from milliseconds to several hours. To answer a `SQL` query, a typical DBMS goes through a series of steps, illustrated in Figure 11.1*:

1. The input query is *parsed* and transformed into an algebraic tree. This step performs both syntactic and semantic checks over the input query, rejecting all invalid requests.
2. The algebraic tree is *optimized* and turned into an execution plan. A query execution plan indicates not only the operations required to evaluate the input query but also the order in which they are performed and the specific algorithms used at each step.
3. The execution plan is either compiled into machine code or interpreted by the execution engine, and results are sent back to the user.

* Note that DBMSs can cache execution plans for repeating input queries and skip the first two steps until the cached plan becomes invalid due to changes in the database design (e.g., an index deletion) or in the data distribution itself.

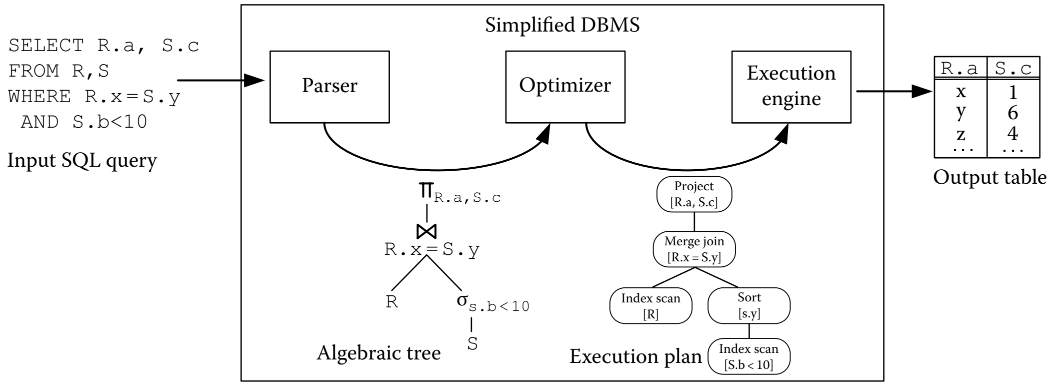

FIGURE 11.1 Executing SQL queries in a relational database system.

Although implementation details vary among specific DBMSs, virtually all optimizers share the same high-level conceptual structure and conduct the search of execution plans in a *cost-based* manner. More specifically, optimizers assign each candidate plan its *estimated* cost and choose the plan with the least expected cost for execution. Alternative formulations attempt to minimize other related metrics, such as the time to obtain the first tuple. Query optimization can therefore be viewed as a complex search problem defined by three interacting components, illustrated in Figure 11.2:

1. Search space: The search space characterizes the set of execution plans that can be considered by the optimizer. For scalability, some optimizers restrict the set of alternatives that can be used to evaluate queries.
2. Cost model: The cost model assigns a cost value to every plan in the search space by estimating the resources consumed by the plan. The quality of the resulting plan is only as good as the underlying cost model.
3. Enumeration strategy: The search space can be characterized without specifying how to generate all candidate plans. The enumeration strategy serves this purpose and dictates how to traverse all interesting plans in the search space efficiently.

The task of an optimizer is nontrivial given the large number of execution plans for an input query, the large variance in response time of the plans in the search space, and the difficulty of accurately estimating costs. A desirable optimizer is one for which (i) the search space includes low-cost plans, (ii) the cost model is accurate, and (iii) the enumeration strategy is efficient.

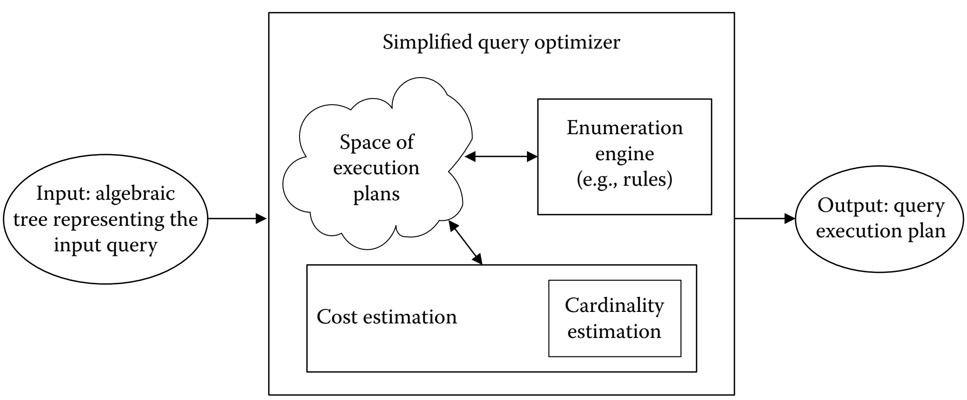

FIGURE 11.2 Architecture of a query optimizer in a DBMS.

The area of query optimization is very rich within the database field. It has been studied in a great variety of contexts and from many different angles, giving rise to diverse solutions in each case. The purpose of this chapter is to primarily discuss the core architecture of modern query optimizers and only touch upon the wealth of results that exist beyond that. Likewise, we make no attempt to provide a complete survey of the literature, in most cases providing only a few example references. More extensive surveys can be found elsewhere [1,2]. The rest of the chapter is organized as follows. Section 11.2 discusses some choices that exist in the space of execution plans and the restrictions usually imposed by current optimizers to make the whole process more manageable. Section 11.3 explains the problem of estimating the cost of execution plans and describes cardinality estimation in more detail, since it is a crucial component in any optimizer cost model. Section 11.4 focuses on enumeration strategies that have been proposed in the context of commercial query optimizers. Section 11.5 touches upon several advanced types of query optimization that have been proposed to address hard problems in the area and raises some open questions in the field. Finally, Section 11.6 concludes the chapter.

11.2 Search Space

The search space of an optimizer depends on the set of physical operators supported by the execution engine and the set of algebraic equivalences among execution subplans. The main source of diversity within an optimizer arises from the available equivalence-preserving transformations.

11.2.1 Operator Reordering

An important class of transformations exploits the commutativity and associativity properties among operators. We next describe three examples of such transformations.

11.2.1.1 Join Reordering

Given a set of relations to be combined in a query, the set of all alternative join trees is determined by two algebraic properties of join: commutativity ($R1 \bowtie R2 \equiv R2 \bowtie R1$), which determines which relations will be inner and outer in the join execution, and associativity [$(R1 \bowtie R2) \bowtie R3 \equiv R1 \bowtie (R2 \bowtie R3)$], which determines the order in which joins will be executed. The alternative join trees that are generated by commutativity and associativity are very large, up to $O(N!)$ for N relations.

Thus, optimizers generally restrict the allowed sequences of join operations to limit the search space and therefore improve optimization time. For example, some optimizers only allow linear sequences of join operations.* Of course, the sequence of joins in an operator tree does not need to be linear. For example, a query joining relations R_1, R_2, R_3, and R_4 can be algebraically represented and evaluated as $(R_1 \bowtie R_2) \bowtie (R_3 \bowtie R_4)$. Such query trees are called bushy and typically require materializing intermediate relations. While bushy trees may result in a cheaper query plan, they considerably increase the cost of enumerating the search space. In general, most optimizers focus on linear join sequences and at most some restricted subsets of bushy join trees.

Another common restriction is to defer Cartesian products until after all joins are processed. This restriction speeds up optimization but may also miss opportunities in some decision-support queries where a single big table joins with multiple small tables. Performing some Cartesian products among these small tables before joining them with the big table can result in a significant reduction in cost.

11.2.1.2 Group-by and Join Clauses

In a conceptual evaluation of a `SQL` query block, the processing of the join precedes that of the group-by. Similarly, a group-by clause in a sub-query in the `FROM` clause is conceptually evaluated before the joins in the outer query block. Some algebraic transformations enable commuting group-by and join

* In a linear sequence of joins, at least one operand in each join is a base relation.

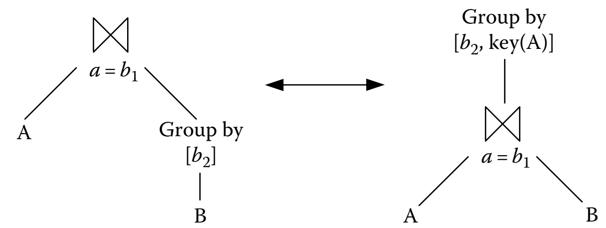

FIGURE 11.3 Reordering joins and group-by clauses.

operators [3,4]. The evaluation of a group-by operator can potentially result in a significant reduction in the number of tuples, since only one tuple is generated for every partition of the relation induced by the group-by. At the same time, joins might eliminate large portions of an input relation, resulting in fewer tuples to subsequently group. Therefore, we can significantly reduce the cost of a query by reordering join and group-by clauses.

As an example of such transformations, a group-by clause can be pulled up above a join, as long as (i) we add a key of the other join relational input to the set of grouping columns and (ii) the join predicate is not defined over an aggregated column, or else the resulting join is not well-formed. Figure 11.3 illustrates this transformation, assuming that b_2 includes b_1 so that the original join is well-formed. Conversely, a group-by clause can be pushed below a join whenever certain conditions are satisfied.

11.2.1.3 Outer Joins

One-sided outer joins are asymmetric operators in SQL that preserve all of the tuples of one relation. For instance, a left outer join between tables R and S, denoted $R \rightarrow S$, is similar to the join $R \bowtie S$, but additionally returns all rows in R that do not match any row in S filling with NULL values all columns in S. Symmetric outer joins preserve both the input relations. Unlike regular joins, a sequence of outer joins and joins do not freely commute. However, the following algebraic equivalence allows to pull outer joins above a block of joins:

$$R \bowtie (S \rightarrow T) \equiv (R \bowtie S) \rightarrow T$$

After outer joins have been delayed in this manner, joins may be freely reordered. There is no guarantee as to which alternative is better in all cases, and thus the use of this transformation needs to be cost-based [5].

11.2.2 Access Path Selection

Earlier query optimizers allowed at most one index for accessing tuples of each table in a given query. For queries with complex single-table predicates, more advanced strategies can manipulate multiple indexes simultaneously to efficiently obtain the qualifying tuples. Consider, as an example, a SQL query that returns information on engineers that earn less than $50,000

```
SELECT *
FROM Emp
WHERE Title = 'Engineer' AND Salary < 50000
```

and suppose that we have single-column indexes $E1 = Emp(Title)$ and $E2 = Emp(Salary)$. Traditionally, the alternative plans that the optimizer considers for the query are either (i) a clustered index scan filtering each tuple by both predicates or (ii) an index seek using either $E1$ or $E2$, followed by lookups to the clustered index to obtain the remaining columns, ended by a filter on the predicate that was not evaluated by the index. By using both indexes simultaneously, we can sometimes obtain

better execution plans. In this case, we could perform what is called an *index intersection* by (i) using index $E1$ to obtain all record identifiers (RIDs) of tuples satisfying `Title = 'Engineer,'` (ii) using index $E2$ to obtain all RIDs of tuples that satisfy `Salary < 50000`, (iii) intersecting both lists of RIDs, and (iv) fetching from the clustered index the resulting records, which satisfy both predicates.

This alternative can greatly reduce execution times because the individual indexes $E1$ and $E2$ are in general smaller than the clustered index, and the intersected list of RIDs can be much smaller than either of the original lists, resulting in much fewer RID lookups.

In general, we can intersect several indexes to answer complex single-table predicates, although at some point the benefit from additional index intersections is outweighed by its cost [6]. Additionally, there are analogous strategies to handle disjunctive predicates using RID unions and negation predicates using RID differences or two seek operations (e.g., employees that are not engineers). Considering these alternatives certainly increases the search space considerably, so some optimizers use heuristics similar to those used for join reordering to limit the number of such index-based alternative plans.

11.2.3 Other Algebraic Transformations

There are several additional transformations that exploit special cases or common patterns, some of which we briefly discuss in the following text:

Query decorrelation: The traditional strategy to process nested queries evaluates the inner sub-query *for each tuple* of the outer sub-query, in what sometimes is called *tuple iteration semantics*. Much work in the literature has identified techniques to decorrelate or *unnest* such queries by "flattening" them into a single block that can be executed more efficiently [7,8]. The complexity of the unnesting problem depends on the structure of the query. The simplest scenarios can be directly unnested using semijoins. The problem is more complex when aggregates are present in the nested sub-query, since unnesting requires pulling up the aggregation without violating the semantics of the nested query, which can be especially tricky in presence of duplicates and `NULL` values.

Partial preaggregation: In some scenarios, rather than fully pushing a group-by below a join, we can unfold a group-by clause into a local, more fine-grained group-by clause, which is pushed below the join, and a global group-by clause, which performs the final aggregation [9]. Such staged computation may still be useful in reducing the join costs because of the data reduction effect of the local aggregate, but requires the aggregate function to satisfy some additional algebraic properties.

Materialized views: Materialized views are results of queries that are stored and used by the optimizer transparently to answer other queries. Given a set of materialized views and a query, the problem is to optimize the query while leveraging available materialized views as much as possible. This problem introduces the challenge of identifying potential reformulations of the query so that it uses one or more of the materialized views [10,11].

Common subexpressions: When intermediate results are defined multiple times in a query, there are opportunities for avoiding multiple identical computations. Several specialized techniques leverage this fact to produce efficient plans that spool and reuse common subexpressions [12].

11.2.4 Implementation Choices

In addition to all the algebraic equivalences discussed so far, the search space also contains alternative implementations for each operator. For instance, joins can be implemented by different algorithms (e.g., hash-based, merge-based, and nested-loop-based), aggregates can be hash- or stream-based, supporting data structures can be built on the fly, and other implementation characteristics of this sort. The optimizer needs to consider different implementations for the same operator because depending on data and environment characteristics, any such alternative can be the most efficient one.

11.3 Cost Model

As we discussed so far, there are many logically equivalent algebraic expressions associated to a given query and multiple ways to implement each of these expressions. Even if we ignore the computational complexity of enumerating the space of possibilities, there remains the question of deciding which of the operator trees consumes the least resources. Resources may be CPU time, I/O cost, memory, or a combination of these. Therefore, given a partial or full operator tree, being able to accurately and efficiently evaluate its cost is of fundamental importance. Cost estimation must be *accurate*, since optimization is only as good as its cost estimates, and *efficient*, since it is in the inner loop of query optimization. The basic framework for estimating costs is based on the following recursive approach:

1. Collect statistical summaries of stored data.
2. Given an operator in the execution plan and statistical summaries for each of its subplans, determine (i) statistical summaries of the output and (ii) the estimated cost of executing the operator, which involves formulas that account the corresponding actions in the operator.

The procedure can be applied to an arbitrary tree to derive the costs of each operator. The estimated cost of a plan is then obtained by combining the costs of each of its operators. The resources needed to execute a query plan, and therefore its cost, is a function of the sizes of the intermediate query results. For that reason, cost estimation heavily depends on cardinality estimates of subplans generated during optimization. The following example illustrates how sizes of intermediate results may significantly change the chosen plan. Consider the following query template, where `@C` is a numeric parameter:

```
SELECT * FROM R,S
WHERE R.x = S.y and R.a < @C
```

Figure 11.4 shows optimal execution plans when `@C` is 20, 200, and 2000. Although the three query instances are syntactically very similar, the resulting plans are rather different. In Figure 11.4a, the number of tuples in *R* satisfying `R.a` < 20 is very small. Consequently, using a non-clustered index over `R.a`, the resulting plan first retrieves the RIDs of all tuples in *R* that satisfy `R.a` < 20. Then, using lookups against table *R*, it lookups the actual tuples that correspond to those RIDs. Finally, it performs a nested-loop join between the subset of tuples of *R* calculated before, and table *S*, which is sequentially scanned. For the case @C = 2000 in Figure 11.4c, the number of tuples of *R* satisfying `R.a` < 2000 is rather large. The resulting plan therefore scans both tables sequentially, discards on the fly tuples from *R* that do not satisfy the condition `R.a` < 2000, and then performs a hash join to obtain the result. (Note that in this scenario, the lookups of the previous plan would have been too numerous and therefore too expensive.) Finally, Figure 11.4b shows the execution plan when the number of tuples of *R* satisfying the predicate is neither too small nor too large. In this case, table *S* is scanned in increasing order of `S.y` using a

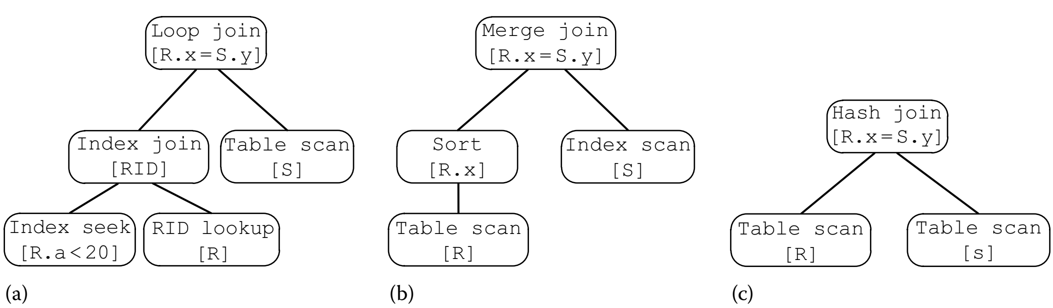

FIGURE 11.4 Query plans for various instances of a template query (a) `R.a` < 20, (b) `R.a` < 200, (c) `R.a` < 2000.

clustered index, and table R is first scanned sequentially discarding invalid tuples as before and then sorted by $R.x$. Finally, a merge join is performed on the two intermediate results.

11.3.1 Statistical Summaries of Data

For every table, statistical information usually includes the number of tuples, the average size of each tuple, the number of physical pages used by the table, and the number of distinct tuples in the table, among others. Statistical information on table columns, if available, is helpful for estimating the cardinality of range or join predicates. A large body of work studies the representation of statistics on a given column or combination of columns. Such alternatives include histograms [13], wavelets [14], sketches [15], sampling [16,17], curve-fitting/parametric information [18], and many others [13]. In most commercial systems, information on the data distribution on a column is provided by histograms, since they can be built and maintained efficiently.

Histograms divide the values of a column or set of columns into a number of buckets, and associate with each bucket some aggregated information. The number of buckets not only influences the accuracy of the histogram, but also affects memory usage, since relevant histograms are loaded into memory during optimization. Both the particular procedure used to select bucket boundaries and the aggregated information associated with each bucket lead to different families of histograms [13]. A popular example is equi-depth histograms, which divide the domain of a column in a table into ranges so that each range has approximately the same number of rows. Other histogram variants, illustrated in Figure 11.5, are equi-width (where the data domain is divided into ranges of equal size), max-diff (where bucket boundaries are placed between pairs of consecutive values that have the largest *frequency gap*), and end-biased (where separate counts are maintained for a small number of very frequent values, and the remaining values are modeled using an equi-depth histogram). Although single-dimensional histograms are widely used, multidimensional histograms are relatively rare in commercial DBMSs.

11.3.2 Cardinality Estimation

Histograms and other statistical structures provide a compressed representation of the underlying column distribution. When manipulating such compact data structures, we generally make a number of simplifying assumptions. For instance, we assume that the tuples in a histogram bucket are distributed uniformly in the bucket domain. In absence of multidimensional statistics, we also assume that predicates in different columns are independent. Using these assumptions, there are simple procedures

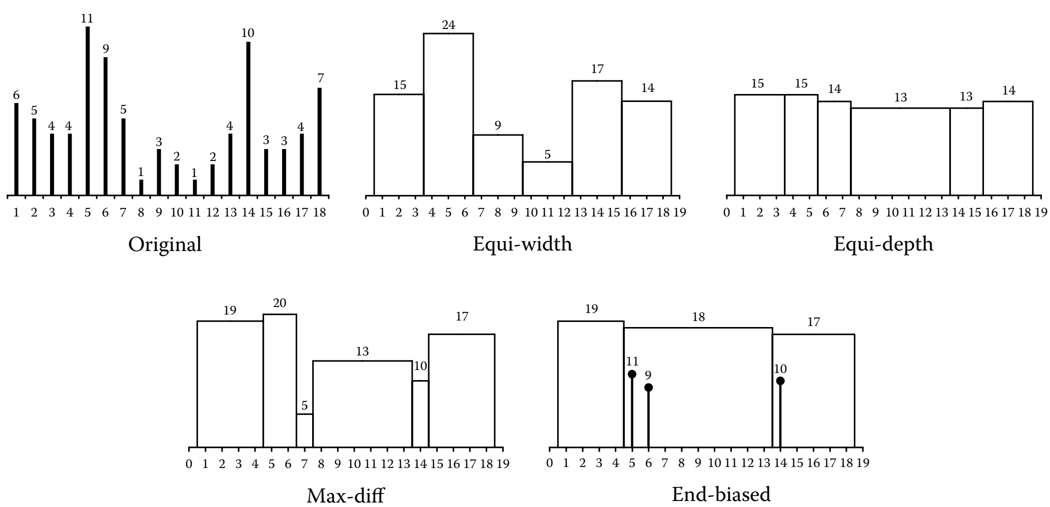

FIGURE 11.5 Histograms approximate value distributions of table columns.

to estimate the number of output tuples for each operator. For instance, to estimate the cardinality of single-table range predicates we use interpolation over the histogram buckets. Join estimation requires that we combine information of two histograms, and involves aligning buckets under certain simplifying assumptions on data distributions. Group-by queries leverage the number of distinct values, stored either globally at the column level, or inside each histogram bucket. Of course, these assumptions only approximate the true cardinality values, and the aforementioned techniques are prone to very large errors in the worst case [19]. To mitigate these problems, some approaches directly store statistics on intermediate expressions and are able to estimate cardinality values without simplifying assumptions whenever the input subexpressions match such intermediate statistics [20].

11.4 Enumeration Strategy

An enumeration algorithm must pick an efficient execution plan for an input query by effectively exploring the search space. An important consideration while designing an enumeration algorithm is to allow it to gracefully adapt to changes in the search space or cost model. Optimization architectures built with this paradigm are called *extensible optimizers*. Building an extensible optimizer does not just involve designing a better enumeration algorithm but also providing an infrastructure for evolution of the optimizer design. In this section, we focus on three representative examples of such extensible optimizers. Rather than providing a detailed description of all the features in these enumeration architectures, we give instead a high-level overview of the frameworks and focus on the aspects that are relevant to our discussion.

11.4.1 Dynamic Programming

System-R was a seminal project that influenced much of the subsequent work in query optimization [21]. The join enumeration algorithm in System-R uses dynamic programming, and it assumes that the cost model satisfies the *principle of optimality*. Specifically, we assume that in order to obtain an optimal plan for a query consisting of *k* joins, it suffices to consider only the optimal plans for query subexpressions that consist of fewer joins and extend those plans with additional joins. In other words, the optimal plan is obtained by combining optimal subplans.

The dynamic programming algorithm, illustrated in Figure 11.6, views the input as a set of relations $\{R_1, \ldots, R_n\}$ to be joined and works in a bottom-up manner. We assume there is an associative array `bestPlan` which, or each subset of tables $\mathcal{R}$, returns the best calculated plan so far for $\mathcal{R}$ First, we generate plans for every table in the query (lines 1 and 2). Such access path selection is encapsulated in function `bestAccessPath` and consists of scans, seeks, or optionally, more complex plans using index intersections and unions. Then, the dynamic programming algorithm performs $n - 1$ iterations in lines 3–8. At the end of the *i-th* iteration, we produce the optimal plans for all subexpressions that join *i* tables. Line 4 considers each subset $\mathcal{R}$ of *i* tables, and line 5 attempts to further partition each such subset into $\mathcal{R}'$ and $\mathcal{R} - \mathcal{R}'$ For each pair of table subsets, line 6 obtains the best plan that joins tables in $\mathcal{R}'$

```
JoinEnumeration ({R1, …, Rn}:input tables)
1   foreach Ri ∈ {R1, …, Rn}
2      bestPlan({Ri}) = bestAccessPath(Ri)
3   for i = 2 to n
4      foreach R ⊂ {R1, …, Rn} such that |R|=i
5         foreach R' ⊂ R such that R' ≠ ∅
6            candPlan = bestJoin(bestPlan(R'), bestPlan(R-R'))
7            if (cost(candPlan) < cost(bestPlan(R)) // cost(null)=∞
8                bestPlan(R) = candPlan
9   return bestPlan({R1, …, Rn})
```

FIGURE 11.6 Dynamic programming algorithm to enumerate joins.

and tables in $\mathcal{R} - \mathcal{R}'$ For that purpose, the procedure `bestJoin` tries different join implementations (e.g., hash-, merge-, and index-based joins). Note that the input to `bestJoin` is `bestPlan`$(\mathcal{R}')$ and `bestPlan`$(\mathcal{R} - \mathcal{R}')$, therefore leveraging the principle of optimality. Lines 7 and 8 update `bestPlan` for the current subset $\mathcal{R}$ based on the cost model. Suboptimal plans are discarded and never considered again. Finally, line 9 returns the best plan for the whole set of tables, which corresponds to the optimal join reordering for the input query. We now supplement the description of the dynamic programming algorithm for join reordering with a couple of important refinements.

First, consider a query that represents the join among $\{R_1, R_2,$ and $R_3\}$ with the predicates $R_1.a = R_2.a = R_3.a$. Let us also assume that the cost of a hash-based join plan for $R_1 \bowtie R_2$ is smaller than that of a merge-based join alternative. In such a case, `bestPlan`$(\{R_1,R_2\})$ would only keep the hash-based join alternative discarding the suboptimal merge-based join. However, note that if merge-based join alternative is used in $R_1 \bowtie R_2$, the result of the join is sorted on columns $R_1.a$ and $R_2.a$. The sorted order may significantly reduce the cost of the subsequent join with R_3. Thus, pruning the merge join alternative for $R_1 \bowtie R_2$ can result in suboptimality of the global plan. The problem arises because the result of the merge join between R_1 and R_2 has an ordering of tuples in the output stream that is useful in a subsequent join. However, the hash-based join alternative, while cheaper locally, does not have such ordering. To address this problem, the dynamic programming algorithm is extended to keep in `bestPlan` an optimal plan for every choice of an *interesting* sort order. Two plans are then compared if they represent the same expression and have the same interesting order.

Second, note that the algorithm in Figure 11.6 enumerates all bushy plans, including those that perform early Cartesian products. The algorithm can easily be adapted to enumerate through different search spaces by suitably modifying line 5. To consider only (left) linear join trees, line 5 is changed to:

$$5\ \textbf{foreach}\ \mathcal{R}' \subset \mathcal{R}\ \texttt{such that}\ |\mathcal{R}'| = 1$$

The strategy discussed in this section was extended several times, culminating in a technique in [22] that efficiently enumerates all bushy trees with no cross products and additionally considers outerjoins.

11.4.2 Rule-Based Systems

In the context of extensible DBMSs, several rule-based strategies have been proposed. Rules are defined on how plans can be constructed or modified, and the enumeration strategy follows the rules to explore the search space. The most representative efforts are those of Starburst [23] and Volcano/Cascades [24,25]. In this section, we briefly describe the Cascades framework, used as the foundation for both academic and industrial query optimizers. This framework works by manipulating *operators*, which are the building blocks of *operator trees* and are used to describe both the input declarative queries and the output execution plans. Consider the simple `SQL` query in the following text:

```
SELECT *
FROM R, S, T
WHERE R.x = S.x AND S.y = T.y
```

Figure 11.7a shows a tree of logical operators that specify, in an almost one-to-one correspondence, the relational algebra representation of the query in the preceding text. In turn, Figure 11.7c shows a tree of physical operators that corresponds to an execution plan for the aforementioned query. The goal of the optimization process is to transform the original logical operator tree into an efficient physical operator tree. For that purpose, Cascades-based optimizers rely on two components: the `MEMO` data structure, which keeps track of the explored search space, and *optimization tasks*, which guide the enumeration strategy.

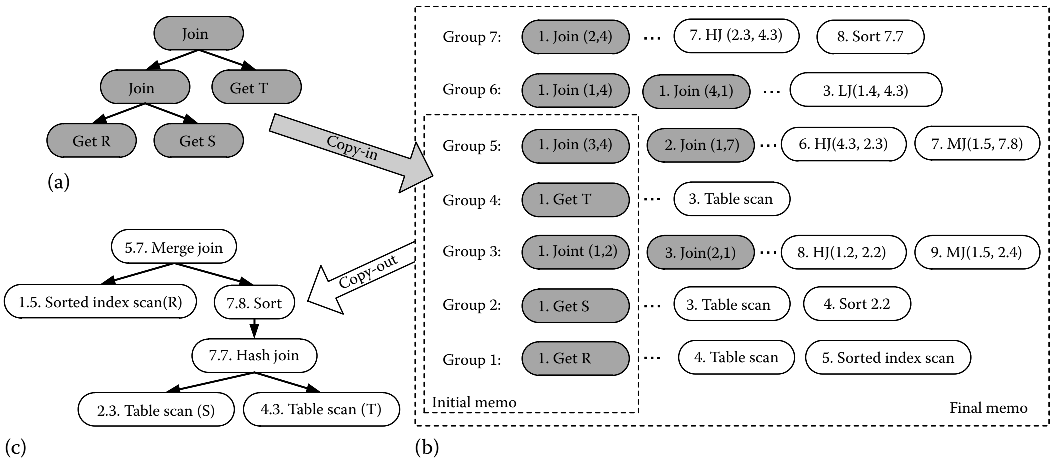

FIGURE 11.7 The MEMO structure in a Cascades optimizer (a) Logical operator tree, (b) MEMO, and (c) physical operator tree.

The MEMO data structure provides a compact representation of the search space of plans by relying on memoization, which is a variant of dynamic programming. A MEMO consists of two key data structures, called *groups* and *groupExpressions*. A *group* represents all equivalent operator trees producing the same output. To reduce memory requirements, a *group* does not explicitly enumerate all its operator trees. Instead, it represents all the operator trees by using *groupExpressions*. A *groupExpression* is an operator having other *groups* as children (rather than other operators). As an example, consider Figure 11.7b, which shows a MEMO for the simple query in the previous section, where logical operators are shaded and physical operators use white background. In the figure, *group* 1 represents all equivalent expressions that return the contents of table *R*. Some operators in *group* 1 are logical (e.g., *Get R*) and some are physical (e.g., *Table Scan* and *Sorted Index Scan*). Likewise, *group* 3 contains all equivalent expressions for $R \bowtie S$. Note that *groupExpression* 3.1, (i.e., *Join(1,2)*), represents all operator trees whose root is *Join*, first child is in *group* 1, and second child is in *group* 2. In this way, a MEMO compactly represents a very large number of operator trees.

The enumeration algorithm in Cascades is divided into several *tasks*. Initially, the optimizer schedules the optimization of the *group* corresponding to the root of the original query tree (*group* 5 in the figure). This task in turn triggers the optimization of smaller and smaller operator subtrees and eventually returns the most efficient execution plan for the input query. At the heart of the optimization tasks there are transformation rules. A transformation rule is a pair of (i) an antecedent expression to match in the MEMO and (ii) a consequent expression to generate and introduce back in the MEMO. On one side, *exploration* rules transform logical operator trees into equivalent logical operator trees, and can range from simple rules like join reordering to more complex ones like pushing aggregates below joins. On the other side, *implementation* rules transform logical operator trees into hybrid logical/physical trees by introducing physical operators into the MEMO. Implementation rules range from simple ones like transforming a logical join into a physical hash join to very complex ones that generate index strategies.

Applying a rule can be broken down into four steps. First, all bindings for the rule antecedent are identified and iterated over (note there can be different ways of matching the antecedent of the rule with operator trees in the current *group*). Second, the rule is applied to each binding generating one or more new expressions. Third, the resulting expressions are integrated back into the MEMO, possibly creating new *groups* (e.g., applying join associativity to expression 5.1 in the figure results in *groupExpression* 5.2, which points to a newly created *group* 7). Finally, each new *groupExpression* triggers new tasks that continue exploring logical equivalences or implement physical plans.

11.4.3 Heuristic Enumeration Strategies

The enumeration strategies discussed so far exhaustively explore the plan search space. Their memory requirements and running time thus grow exponentially with query size in the worst case. For that reason, many modern systems have a limit on the size of queries that can be exhaustively optimized (usually around 15 joins). Beyond these limits, query optimizers apply heuristics to enumerate a fraction of the search space or use faster specialized strategies for special cases. As an example of the latter approach, it is known that for chain queries, the classical dynamic programming algorithm works in polynomial time [26]. Also, if the join graph is acyclic and the cost model satisfies the adjacent sequence interchange (ASI) property [27], the IKKBZ technique in [28] returns the optimal plan in $\mathcal{O}(N^2)$ where N is the number of tables.

To effectively address more complex scenarios, heuristic enumeration strategies are proposed, which explore only a fraction of the search space. One line of work adapts randomized techniques and combinatorial heuristics to address this problem, and considers the space of plans as points in a high-dimensional space, that can be *traversed* via transformations (e.g., join commutativity and associativity). Such strategies include iterative improvement, simulated annealing, and genetic algorithms [29] and can be seen as heuristic variations of transformation-based exhaustive enumeration algorithms. Another line of work implements heuristic variations of dynamic programming. Some notable approaches include iteratively performing dynamic programming on a subset of tables and replacing intermediate results with a new *virtual* table [30], simplifying the initial join graph by disallowing non-promising join edges and exhaustively searching the resulting simpler problem [31], and greedily building execution trees one operator at a time [32,33].

11.5 Advanced Optimization Topics

In this section, we discuss some advanced types of optimization that researchers have proposed over the past few years, and for which fundamental questions remain open. The descriptions are based on examples only; further details may be found in the references provided. Furthermore, there are several research challenges that we do not discuss at all due to space limitations, although much interesting work has been and remains to be done on them, such as query optimizer generators; query optimizer validation; and domain-specific query optimization, such as object-oriented, heterogeneous, recursive, XML-based, stream-based, and probabilistic-based, among others.

11.5.1 Parallel/Distributed Optimization

A parallel DBMS is typically an individual system controlling multiple processors that are in the same location. When multiple processors are available, each operator in the query tree can be parallelized by partitioning the input among available processors and later combining results using intraoperator parallelism. Additionally, there are multiple choices to place operators into groups that should be executed simultaneously by the available processors, called interoperator parallelism and further divided into pipelining and independent parallelism. Parallelism can reduce the overall time to process a query, but is associated with much larger search spaces over traditional sequential environments. For that reason, most systems and research prototypes adopt heuristics to avoid dealing with a very large search space. One popular approach first identifies the optimal sequential plan using conventional techniques and then identifies the optimal parallelization/scheduling of that plan [34]. Other approaches only consider schedules that process memory-resident right-deep segments of possibly bushy query plans one at a time with no independent interoperator parallelism [35,36]. More recent strategies integrate parallel plan optimization mode deeply into the query optimizer, instead of being done during postoptimization [37]. With recent growing interest in large-scale computation, parallel optimization remains an active research area.

Distributed Databases are composed of semiautonomous processing sites that are connected via a network that could be spread over a large geographic area. Many prototypes of distributed DBMSs have been implemented [38,39], and several commercial systems offer distributed versions of their products as well. The main differences between centralized and distributed query optimization is in the search space, which additionally contains various processing strategies and opportunities for transmitting data among sites. The most well-known opportunity is to preprocess joins use semijoins in order to only transmit tuples that would certainly contribute to join results [38]. An extension of that idea is using Bloom filters, which are bit vectors that approximate join columns and are transferred across sites to determine which tuples might participate in a join so that only these may be transmitted [39].

11.5.2 Parametric Query Optimization

Many commercial applications rely on precompiled parameterized queries to interact with a database. The DBMS optimizes and caches a parameterized query the first time it is submitted and then reuses the cached execution plan when the query is resubmitted with different parameter values. This approach is especially useful for relatively simple queries, as each optimization call may be a significant fraction of the total execution time. Unfortunately, executing a cached query with a set of parameters different from those used at compilation may be suboptimal. Parametric query optimization addresses this problem by exhaustively determining the optimal plans in each point of the parameter space at compile time. A parametric optimizer determines a set of plans such that, for each point in the parameter space, there is at least one plan in the set that it is optimal. At runtime, these techniques use the actual parameter values and simply pick the plan that was found optimal for them with little or no overhead. Parametric optimization proposals often assume that the cost formulas of physical plans are linear or piecewise linear with respect to the cost parameters or that the regions of optimality are connected and convex. Various approaches to parametric query optimization include dynamic plans [40], randomized algorithms [41], and non-intrusive procedures on top of traditional query optimizers [42]. Recent work provides interesting and actionable diagrams of the plan choices of the optimizer over a space of input parameters [43]. Although much work has been done in the area of parametric optimization, there is still significant room for improvement, especially in the context of industry-strength database systems.

11.5.3 Adaptive Query Processing

Traditional approaches to query processing can be crisply divided into query optimization (which produces an execution plan) and execution proper (which evaluates the plan and obtains results). The quality of the resulting execution plan depends, to a large extent, on (i) the cost model and underlying cardinality estimations being accurate and (ii) the absence of variability in the environment variables used during optimization (e.g., available memory). In real scenarios, however, both these assumptions are not valid, and thus execution plans can be highly suboptimal. This problem motivates *intra-query adaptivity*, which essentially attempts to somehow interleave query optimization and execution, allowing the system to correct bad choices as soon as possible [44]. A simple approach uses execution feedback to progressively improve the statistical information used during optimization [18,45]. More dynamic approaches to address this problem insert checkpoints in the execution plan that monitor actual cardinality values during execution. If the actual intermediate results are very different from the estimated ones, the system suspends the execution of the query, reoptimizes it using the new information, and chooses whether to continue with the original plan or switch to a new one [46,47]. An extreme approach continuously reorders operators in a query plan as it runs, conceptually considering different plans for each routed tuple [48]. Adaptive query processing is a topic that received much attention lately, but has not yet fully found its way into commercial systems.

11.5.4 Multiquery Optimization

So far, this chapter focused on optimizing individual queries. Quite often, however, multiple queries become available for optimization at roughly the same time. Instead of optimizing each query separately, we may obtain a *global* plan that, although suboptimal for each individual query, is optimal for the execution of all of them as a group [49]. Consider the following queries:

```
Q1 =   SELECT Emp.Name                Q2 =   SELECT Dept.floor, Emp.Name
       FROM Emp, Dept                        FROM Emp, Dept
       WHERE ON Emp.id = Dept.id             WHERE ON Emp.id = Dept.id
       AND Dept.Budget > 1M                  AND Emp.Title = 'Programmer'
```

Depending on the sizes of the `Emp` and `Dept` relations and the selectivities of the predicates, it may well be that computing the entire join once and then applying the two predicates are more efficient than doing the join twice, each time taking into account the corresponding predicate.

11.5.5 Semantic Optimization

Semantic query optimization is a form of optimization that uses integrity constraints defined in the database to rewrite a given query into semantically equivalent ones [50,51]. These can then be optimized as regular queries, and the most efficient plan among all can be used to answer the original query. Examples of semantic optimization include introduction of inferred predicates, removal of joins under foreign key constraints when only columns from the primary table are used, and inference about distinct values for grouping queries. As a simple example, consider an integrity constraint on table `Emp` of the form `Title = "Programmer" ⇒ salary > 100K` and the following query:

```
SELECT name, floor
from Emp JOIN Dept ON Emp.id = Dept.id
WHERE Title = "Programmer"
```

Using this constraint, the query can be rewritten into an equivalent one that includes an extra predicate `salary > 100 K`, which results in an efficient plan if the only available index is on `Emp.salary`.

```
SELECT name, floor
from Emp JOIN Dept ON Emp.id = Dept.id
WHERE Title = "Programmer" AND salary > 100K
```

Semantic optimization is a relatively old topic that periodically finds renewed interest in the research community.

11.5.6 Physical Database Design

DBMSs provide physical data independence, so that queries return the same result independently of the set of available indexes. Of course, the *performance* of evaluating queries will significantly vary depending on index availability. Together with the capabilities of the execution engine and query optimizer, the physical design of a database determines how efficiently a query is ultimately executed. For this reason, there has been a great amount of interest in automatically deciding, for a given query workload, what would be a reasonably good index configuration to materialize and maximize query processing performance [52]. Physical database design is a complex search problem over the space of available indexes, and current solutions iterate over different index configurations evaluating the benefit of such

index subsets. These solutions require evaluating the expected cost of a query under a given candidate index configuration in the search space. To do so in a scalable manner, optimizers are typically extended with a new interface that *simulates* a hypothetical index configuration in the DBMS and optimize queries without actually materializing new indexes, a process called *what-if optimization*. What-if optimization is a cornerstone of automated physical database design, which enabled virtually all commercial tuners. It is also one of the first scenarios in which the query optimizer itself is made into the inner loop of an even larger application. Relying on a query optimizer to recommend physical design changes is a novel research direction that found significant interest in the industry, and is currently being actively refined and generalized in the research community.

11.6 Conclusion

To a large extent, the success of a DBMS lies in the quality, functionality, and sophistication of its query optimizer. In this chapter, we gave a bird's eye view of query optimization, presented an abstraction of the architecture of a query optimizer, and focused on the techniques currently used by most commercial systems. In addition, we provided a glimpse of advanced issues in query optimization, whose solutions are still partial and have not completely found their way into commercial systems. Although query optimization has existed as a field for more than 30 years, it is very surprising how fresh it remains in terms of being a source of research problems, as illustrated in the previous section. At the same time, in virtually every component of the traditional optimization architecture of Figure 11.2, there are crucial questions for which we do not have complete answers. When is it worthwhile to consider bushy trees instead of just linear trees? How can buffering and other runtime variables be effectively modeled in the cost formulas? Which search strategy can be used for complex queries with reliability and confidence? We believe that the future in query optimization will be as active as the past and will bring many advances to optimization technology, changing many of the approaches currently used in practice. Despite its age, query optimization remains an exciting field.

Acknowledgment

I thank Ravi Ramamurthy for many useful comments that improved the presentation and content of this chapter. Portions of this chapter also appeared in earlier papers and book chapters [52,53].

Concurrency Control and Recovery

Michael J. Franklin
University of California at Berkeley

12.1 Introduction

Many service-oriented businesses and organizations, such as banks, airlines, catalog retailers, and hospitals, have grown to depend on fast, reliable, and correct access to their "mission-critical" data on a constant basis. In many cases, particularly for global enterprises, 7 × 24 access is required, that is, the data must be available 7 days a week, 24 h a day. *Database management systems* (DBMSs) are often employed to meet these stringent performance, availability, and reliability demands. As a result, two of the core functions of a DBMS are (1) to protect the data stored in the database and (2) to provide correct and highly available access to those data in the presence of concurrent access by large and diverse user populations, despite various software and hardware failures. The responsibility for these functions resides in the *concurrency control* and *recovery* components of the DBMS software. *Concurrency control* ensures that individual users see consistent states of the database even though operations on behalf of many users may be interleaved by the database system. *Recovery* ensures that the database is fault-tolerant, that is, that the database state is not corrupted as the result of a software, system, or media failure. The existence of this functionality in the DBMS allows applications to be written without explicit concern for concurrency and fault tolerance. This freedom provides a tremendous increase in programmer productivity and allows new applications to be added more easily and safely to an existing system.

For database systems, correctness in the presence of concurrent access and/or failures is tied to the notion of a *transaction*. A transaction is a unit of work, possibly consisting of multiple data accesses and updates that must *commit* or *abort* as a single atomic unit. When a transaction *commits*, all updates that it performed on the database are made permanent and visible to other transactions. In contrast, when a transaction *aborts*, all of its updates are removed from the database, and the database is restored (if necessary) to the state it would have been in if the aborting transaction had never been executed.

Informally, transaction executions are said to respect the *atomicity, consistency, isolation, and durability* (*ACID*) *properties* (Gray and Reuter 1993):

Atomicity: This is the "all-or-nothing" aspect of transactions discussed earlier—either all operations of a transaction complete successfully or none of them do. Therefore, after a transaction has completed (i.e., committed or aborted), the database will not reflect a partial result of that transaction.

Consistency: Transactions preserve the consistency of the data—a transaction performed on a database that is internally consistent will leave the database in an internally consistent state. Consistency is typically expressed as a set of declarative *integrity constraints*. For example, a constraint may be that the salary of an employee cannot be higher than that of his or her manager.

Isolation: A transaction's behavior is not impacted by the presence of other transactions that may be accessing the same database concurrently. That is, a transaction sees only a state of the database that could occur if that transaction were the only one running against the database and produces only results that it could produce if it was running alone.

Durability: The effects of *committed* transactions survive failures. Once a transaction commits, its updates are guaranteed to be reflected in the database even if the contents of volatile (e.g., main memory) or nonvolatile (e.g., disk) storage are lost or corrupted.

Of these four transaction properties, the concurrency control and recovery components of a DBMS are primarily concerned with preserving *atomicity*, *isolation*, and *durability*. The preservation of the *consistency* property typically requires additional mechanisms such as compile-time analysis or run-time triggers in order to check adherence to integrity constraints.* For this reason, this chapter focuses primarily on the A, I, and D of the ACID transaction properties.

Transactions are used to structure complex processing tasks, which consist of multiple data accesses and updates. A traditional example of a transaction is a money transfer from one bank account (say account A) to another (say B). This transaction consists of a withdrawal from A and a deposit into B and requires four accesses to account information stored in the database: a read and write of A and a read and write of B. The data accesses of this transaction are as follows:

```
TRANSFER()
  01 A_bal: = Read(A)
  02 A_bal: = A bal – $50
  03 Write(A, A_bal)
  04 B_bal: = Read(B)
  05 B_bal: = B_bal + $50
  06 Write(B, B_bal)
```

The value of A in the database is read and decremented by $50, and then the value of B in the database is read and incremented by $50. Thus, TRANSFER preserves the invariant that the sum of the balances of A and B prior to its execution must equal the sum of the balances after its execution, regardless of whether the transaction commits or aborts.

Consider the importance of the atomicity property. At several points during the TRANSFER transaction, the database is in a temporarily inconsistent state. For example, between the time that account A is updated (statement 3) and the time that account B is updated (statement 6), the database reflects the decrement of A but not the increment of B, so it appears as if $50 has disappeared from the database. If the transaction reaches such a point and then is unable to complete (e.g., due to a failure or an unresolvable conflict), then the system must ensure that the effects of the partial results of the transaction (i.e., the update to A) are removed from the database—otherwise the database state will be

* In the case of triggers, the recovery mechanism is typically invoked to abort an offending transaction.

incorrect. The durability property, in contrast, only comes into play in the event that the transaction successfully commits. Once the user is notified that the transfer has taken place, he or she will assume that account B contains the transferred funds and may attempt to use those funds from that point on. Therefore, the DBMS must ensure that the results of the transaction (i.e., the transfer of the $50) remain reflected in the database state even if the system crashes.

Atomicity, consistency, and durability address correctness for *serial execution* of transactions where only a single transaction at a time is allowed to be in progress. In practice, however, DBMSs typically support *concurrent execution*, in which the operations of multiple transactions can be executed in an interleaved fashion. The motivation for concurrent execution in a DBMS is similar to that for multiprogramming in operating systems, namely, to improve the utilization of system hardware resources and to provide multiple users a degree of fairness in access to those resources. The *isolation* property of transactions comes into play when concurrent execution is allowed.

Consider a second transaction that computes the sum of the balances of accounts A and B:

```
ReportSum()
  01 A_bal: = Read(A)
  02 B_bal: = Read(B)
  03 Print(A_bal + B_bal)
```

Assume that initially, the balance of account A is $300 and the balance of account B is $200. If a ReportSum transaction is executed on this state of the database, it will print a result of $500. In a database system restricted to *serial execution* of transactions, ReportSum will also produce the same result if it is executed after a Transfer transaction. The atomicity property of transactions ensures that if the Transfer aborts, all of its effects are removed from the database (so ReportSum would see A = $300 and B = $200), and the durability property ensures that if it commits, then all of its effects remain in the database state (so ReportSum would see A = $250 and B = $250).

Under concurrent execution, however, a problem could arise if the isolation property is not enforced. As shown in Table 12.1, if ReportSum were to execute after Transfer has updated account A but before it has updated account B, then ReportSum could see an inconsistent state of the database. In this case, the execution of ReportSum sees a state of the database in which $50 has been withdrawn from account A but has not yet been deposited in account B, resulting in a total of $450—it seems that $50 has disappeared from the database. This result is not one that could be obtained in any serial execution of Transfer and ReportSum transactions. It occurs because in this example, ReportSum accessed the database when it was in a temporarily inconsistent state. This problem is sometimes referred to as the *inconsistent retrieval* problem. To preserve the isolation property of transactions, the DBMS must prevent the occurrence of this and other potential anomalies that could arise due to concurrent execution. The formal notion of correctness for concurrent execution in database systems is known as *serializability* and is described in Section 12.2.

Although the transaction processing literature often traces the history of transactions back to antiquity (such as Sumerian tax records) or to early contract law (Gray 1981, Gray and Reuter 1993,

TABLE 12.1 An Incorrect Interleaving of Transfer and ReportSum

Transfer	ReportSum	
01 A_bal: = Read (A)		
02 A_bal: = A_bal - $50		
03 Write(A, A_bal)		
	01 A_bal: = Read (A)	/* value is $250 */
	02 B_bal: = Read (B)	/* value is $200 */
	03 Print (A_bal + B_bal)	/* value is $450 */
04 B_bal: = Read (B)		
05 B_bal: = B_bal + $50		
06 Write (B,B_bal)		

Korth 1995), the roots of the transaction concept in information systems are typically traced back to the early 1970s and the work of Bjork (1973) and Davies (1973). Early systems such as IBM's IMS addressed related issues, and a systematic treatment and understanding of ACID transactions was developed several years later by members of the IBM System R group (Gray et al. 1975, Eswaran et al. 1976) and others (e.g., Lomet 1977, Rosenkrantz et al. 1977). Since that time, many techniques for implementing ACID transactions have been proposed, and a fairly well-accepted set of techniques has emerged. The remainder of this chapter contains an overview of the basic theory that has been developed as well as a survey of the more widely known implementation techniques for concurrency control and recovery. A brief discussion of work on extending the simple transaction model is presented at the end of the chapter.

It should be noted that issues related to those addressed by concurrency control and recovery in database systems arise in other areas of computing systems as well, such as file systems and memory systems. There are, however, two salient aspects of the ACID model that distinguish transactions from other approaches. First is the incorporation of both isolation (concurrency control) and fault tolerance (recovery) issues. Second is the concern with treating arbitrary groups of *write* and/or *read* operations on multiple data items as atomic, isolated units of work. While these aspects of the ACID model provide powerful guarantees for the protection of data, they also can induce significant systems implementation complexity and performance overhead. For this reason, the notion of ACID transactions and their associated implementation techniques have remained largely within the DBMS domain, where the provision of highly available and reliable access to "mission-critical" data is a primary concern.

12.2 Underlying Principles

12.2.1 Concurrency Control

12.2.1.1 Serializability

As stated in the previous section, the responsibility for maintaining the isolation property of ACID transactions resides in the concurrency control portion of the DBMS software. The most widely accepted notion of correctness for concurrent execution of transactions is *serializability*. Serializability is the property that an (possibly interleaved) execution of a group of transactions has the same effect on the database, and produces the same output, as some serial (i.e., noninterleaved) execution of those transactions. It is important to note that serializability does not specify any *particular* serial order, but rather, only that the execution is equivalent to *some* serial order. This distinction makes serializability a slightly less intuitive notion of correctness than transaction initiation time or commit order, but it provides the DBMS with significant additional flexibility in the scheduling of operations. This flexibility can translate into increased responsiveness for end users.

A rich theory of database concurrency control has been developed over the years (see Papadimitriou 1986, Bernstein et al. 1987, Gray and Reuter 1993), and serializability lies at the heart of much of this theory. In this chapter, we focus on the simplest models of concurrency control, where the operations that can be performed by transactions are restricted to *read*(x), *write*(x), *commit*, and *abort*. The operation *read*(x) retrieves the value of a data item from the database, *write*(x) modifies the value of a data item in the database, and *commit* and *abort* indicate successful or unsuccessful transaction completion, respectively (with the concomitant guarantees provided by the ACID properties). We also focus on a specific variant of serializability called *conflict serializability*. Conflict serializability is the most widely accepted notion of correctness for concurrent transactions because there are efficient, easily implementable techniques for detecting and/or enforcing it. Another well-known variant is called *view serializability*. View serializability is less restrictive (i.e., it allows more legal schedules) than conflict serializability, but it and other variants are primarily of theoretical interest because they are impractical to implement. The reader is referred to Papadimitriou (1986) for a detailed treatment of alternative serializability models.

12.2.1.2 Transaction Schedules

Conflict serializability is based on the notion of a *schedule* of transaction operations. A schedule for a set of transaction executions is a partial ordering of the operations performed by those transactions, which shows how the operations are interleaved. The ordering defined by a schedule can be partial in the sense that it is only required to specify two types of dependencies:

1. All operations of a given transaction for which an order is specified by that transaction must appear in that order in the schedule. For example, the definition of ReportSum in the preceding text specifies that account A is read before account B.
2. The ordering of all *conflicting operations* from different transactions must be specified. Two operations are said to conflict if they both operate on the same data item and at least one of them is a *write*().

The concept of a schedule provides a mechanism to express and reason about the (possibly) concurrent execution of transactions. A *serial* schedule is one in which all the operations of each transaction appear consecutively. For example, the serial execution of Transfer followed by ReportSum is represented by the following schedule:

$$r_0[A] \to w_0[A] \to r_0[B] \to w_0[B] \to c_0 \to r_1[A] \to r_1[B] \to c_1 \tag{12.1}$$

In this notation, each operation is represented by its initial letter, the subscript of the operation indicates the *transaction number* (tn) of the transaction on whose behalf the operation was performed, and a capital letter in brackets indicates a specific data item from the database (for read and write operations). A tn is a unique identifier that is assigned by the DBMS to an execution of a transaction. In the example earlier, the execution of Transfer was assigned tn 0 and the execution of ReportSum was assigned tn 1. A right arrow (→) between two operations indicates that the left-hand operation is ordered before the right-hand one. The ordering relationship is transitive; the orderings implied by transitivity are not explicitly drawn.

For example, the interleaved execution of Transfer and ReportSum shown in Table 12.1 would produce the following schedule:

$$r_0[A] \to w_0[A] \to r_1[A] \to r_1[B] \to c_1 \to r_0[B] \to w_0[B] \to c_0 \tag{12.2}$$

The formal definition of serializability is based on the concept of equivalent schedules. Two schedules are said to be *equivalent* (≡) if

1. They contain the same transactions and operations.
2. They order all conflicting operations of non-aborting transactions in the same way.

Given this notion of equivalent schedules, *a schedule is said to be serializable if and only if it is equivalent to some serial schedule*. For example, the following concurrent schedule is serializable because it is equivalent to schedule 12.1:

$$r_0[A] \to w_0[A] \to r_1[A] \to r_0[B] \to w_0[B] \to c_0 \to r_1[B] \to c_1 \tag{12.3}$$

In contrast, the interleaved execution of schedule 12.2 is *not* serializable. To see why, notice that in any serial execution of Transfer and ReportSum either *both* writes of Transfer will precede *both* reads of ReportSum or vice versa. However, in schedule 12.2 $w_0[A] \to r_1[A]$ but $r_1[B] \to w_0[b]$. schedule 12.2, therefore, is not equivalent to any possible serial schedule of the two transactions so it is not serializable. This result agrees with our intuitive notion of correctness, because recall that schedule 12.2 resulted in the apparent loss of $50.

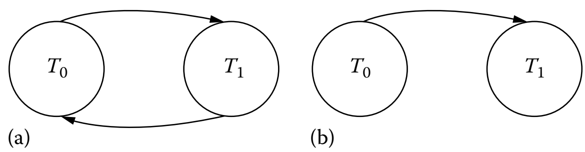

FIGURE 12.1 Precedence graphs for (a) nonserializable and (b) serializable schedules.

12.2.1.3 Testing for Serializability

A schedule can easily be tested for serializability through the use of a *precedence graph*. A precedence graph is a directed graph that contains a vertex for each *committed* transaction execution in a schedule (noncommitted executions can be ignored). The graph contains an edge from transaction execution T_i to transaction execution T_j ($i \neq j$) if there is an operation in T_i that is constrained to precede an operation of T_j in the schedule. A schedule is serializable if and only if its precedence graph is *acyclic*. Figure 12.1a shows the precedence graph for schedule 12.2. That graph has an edge $T_0 \rightarrow T_1$ because the schedule contains $w_0[A] \rightarrow r_1[A]$ and an edge $T_1 \rightarrow T_0$ because the schedule contains $r_1[B] \rightarrow w_0[b]$. The cycle in the graph shows that the schedule is nonserializable. In contrast, Figure 12.1b shows the precedence graph for schedule 12.1. In this case, all ordering constraints are from T_0 to T_1, so the precedence graph is acyclic, indicating that the schedule is serializable.

There are a number of practical ways to implement conflict serializability. These and other implementation issues are addressed in Section 12.3. Before discussing implementation issues, however, we first survey the basic principles underlying database recovery.

12.2.2 Recovery

12.2.2.1 Coping with Failures

Recall that the responsibility for the atomicity and durability properties of ACID transactions lies in the recovery component of the DBMS. For recovery purposes, it is necessary to distinguish between two types of storage: (1) *volatile storage*, such as main memory, whose state is lost in the event of a system crash or power outage and (2) *nonvolatile storage*, such as magnetic disks or tapes, whose contents persist across such events. The recovery subsystem is relied upon to ensure correct operation in the presence of three different types of failures (listed in order of likelihood):

1. *Transaction failure*: When a transaction that is in progress reaches a state from which it cannot successfully commit, all updates that it made must be removed from the database in order to preserve the atomicity property. This is known as *transaction rollback*.
2. *System failure*: If the system fails in a way that causes the loss of volatile memory contents, recovery must ensure that (1) the updates of all transactions that had committed prior to the crash are reflected in the database and (2) all updates of other transactions (aborted or in progress at the time of the crash) are removed from the database.
3. *Media failure*: In the event that data are lost or corrupted on the nonvolatile storage (e.g., due to a disk-head crash), then the online version of the data is lost. In this case, the database must be restored from an archival version of the database and brought up to date using operation logs.

In this chapter, we focus on the issues of rollback and crash recovery, the most frequent uses of the DBMS recovery subsystem. Recovery from media crashes requires substantial additional mechanisms and complexity beyond what is covered here. Media recovery is addressed in the recovery-related references listed at the end of this chapter.

12.2.2.2 Buffer Management Issues

The process of removing the effects of an incomplete or aborted transaction for preserving atomicity is known as *UNDO*. The process of reinstating the effects of a committed transaction for durability

is known as *REDO*. The amount of work that a recovery subsystem must perform for either of these functions depends on how the DBMS buffer manager handles data that are updated by in-progress and/or committing transactions (Haerder and Reuter 1983, Bernstein et al. 1987). Recall that the buffer manager is the DBMS component that is responsible for coordinating the transfer of data between main memory (i.e., volatile storage) and disk (i.e., nonvolatile storage). The unit of storage that can be written atomically to nonvolatile storage is called a *page*. Updates are made to copies of pages in the (volatile) buffer pool, and those copies are written out to nonvolatile storage at a later time. If the buffer manager allows an update made by an *uncommitted* transaction to overwrite the most recent committed value of a data item on nonvolatile storage, it is said to support a *STEAL* policy (the opposite is called *NO-STEAL*). If the buffer manager ensures that all updates made by a transaction are reflected on nonvolatile storage before the transaction is allowed to commit, then it is said to support a *FORCE* policy (the opposite is *NO-FORCE*).

Support for the STEAL policy implies that in the event that a transaction needs to be rolled back (due to transaction failure or system crash), UNDOing the transaction will involve restoring the values of any nonvolatile copies of data that were overwritten by that transaction back to their previous committed state. In contrast, a NO-STEAL policy guarantees that the data values on nonvolatile storage are valid, so they do not need to be restored. A NO-FORCE policy raises the possibility that some committed data values may be lost during a system crash because there is no guarantee that they have been placed on nonvolatile storage. This means that substantial REDO work may be required to preserve the durability of committed updates. In contrast, a FORCE policy ensures that the committed updates *are* placed on nonvolatile storage, so that in the event of a system crash, the updates will still be reflected in the copy of the database on nonvolatile storage.

From the earlier discussion, it should be apparent that a buffer manager that supports the combination of NO-STEAL and FORCE would place the fewest demands on UNDO and REDO recovery. However, these policies may negatively impact the performance of the DBMS during normal operation (i.e., when there are no crashes or rollbacks) because they restrict the flexibility of the buffer manager. NO-STEAL obligates the buffer manager to retain updated data in memory until a transaction commits or to write those data to a temporary location on nonvolatile storage (e.g., a swap area). The problem with a FORCE policy is that it can impose significant disk write overhead during the critical path of a committing transaction. For these reasons, many buffer managers support the STEAL and NO-FORCE (*STEAL/NO-FORCE*) policies.

12.2.2.3 Logging

In order to deal with the UNDO and REDO requirements imposed by the STEAL and NO-FORCE policies, respectively, database systems typically rely on the use of a *log*. A log is a sequential file that stores information about transactions and the state of the system at certain instances. Each entry in the log is called a *log record*. One or more log records are written for each update performed by a transaction. When a log record is created, it is assigned a *log sequence number* (LSN), which serves to uniquely identify that record in the log. LSNs are typically assigned in a monotonically increasing fashion so that they provide an indication of relative position in the log. When an update is made to a data item in the buffer, a log record is created for that update. Many systems write the LSN of this new log record into the page containing the updated data item. Recording LSNs in this fashion allows the recovery system to relate the state of a data page to logged updates in order to tell if a given log record is reflected in a given state of a page.

Log records are also written for transaction management activities such as the commit or abort of a transaction. In addition, log records are sometimes written to describe the state of the system at certain periods of time. For example, such log records are written as part of the *checkpointing* process. Checkpoints are taken periodically during normal operation to help bound the amount of recovery work that would be required in the event of a crash. Part of the checkpointing process involves the writing of one or more *checkpoint records*. These records can include information about the contents of

the buffer pool and the transactions that are currently active. The particular contents of these records depend on the method of checkpointing that is used. Many different checkpointing methods have been developed, some of which involve quiescing the system to a consistent state, while others are less intrusive. A particularly nonintrusive type of checkpointing is used by the ARIES recovery method (Mohan et al. 1992) that is described in Section 12.3.

For transaction update operations, there are two basic types of logging: *physical* and *logical* (Gray and Reuter 1993). Physical log records typically indicate the location (e.g., position on a particular page) of modified data in the database. If support for UNDO is provided (i.e., a STEAL policy is used), then the value of the item prior to the update is recorded in the log record. This is known as the *before image* of the item. Similarly the *after image* (i.e., the new value of the item after the update) is logged if REDO support is provided. Thus, physical log records in a DBMS with STEAL/NO-FORCE buffer management contain both the old and new data values of items. Recovery using physical log records has the property that recovery actions (i.e., UNDOs or REDOs) are *idempotent*, meaning that they have the same effect no matter how many times they are applied. This property is important if recovery is invoked multiple times, as will occur if a system fails repeatedly (e.g., due to a power problem or a faulty device).

Logical logging (sometimes referred to as *operational logging*) records only high-level information about operations that are performed, rather than recording the actual changes to items (or storage locations) in the database. For example, the insertion of a new tuple into a relation might require many physical changes to the database such as space allocation, index updates, and reorganization. Physical logging would require log records to be written for all of these changes. In contrast, logical logging would simply log the fact that the insertion had taken place, along with the value of the inserted tuple. The REDO process for a logical logging system must determine the set of actions that are required to fully reinstate the insert. Likewise, the UNDO logic must determine the set of actions that make up the inverse of the logged operation.

Logical logging has the advantage that it minimizes the amount of data that must be written to the log. Furthermore, it is inherently appealing because it allows many of the implementation details of complex operations to be hidden in the UNDO/REDO logic. In practice, however, recovery based on logical logging is difficult to implement because the actions that make up the logged operation are not performed atomically. That is, when a system is restarted after a crash, the database may not be in an *action consistent* state with respect to a complex operation—it is possible that only a subset of the updates made by the action had been placed on nonvolatile storage prior to the crash. As a result, it is difficult for the recovery system to determine which portions of a logical update are reflected in the database state upon recovery from a system crash. In contrast, physical logging does not suffer from this problem, but it can require substantially higher logging activity.

In practice, systems often implement a compromise between physical and logical approaches that has been referred to as *physiological logging* (Gray and Reuter 1993). In this approach, log records are constrained to refer to a single page, but may reflect logical operations on that page. For example, a physiological log record for an insert on a page would specify the value of the new tuple that is added to the page, but would not specify any free-space manipulation or reorganization of data on the page resulting from the insertion; the REDO and UNDO logic for insertion would be required to infer the necessary operations. If a tuple insert required updates to multiple pages (e.g., data pages plus multiple index pages), then a separate physiological log record would be written for each page updated. Physiological logging avoids the action consistency problem of logical logging, while reducing, to some extent, the amount of logging that would be incurred by physical logging. The ARIES recovery method is one example of a recovery method that uses physiological logging.

12.2.2.4 Write-Ahead Logging

A final recovery principle to be addressed in this section is the *write-ahead logging* (WAL) protocol. Recall that the contents of volatile storage are lost in the event of a system crash. As a result, any log records that are not reflected on nonvolatile storage will also be lost during a crash. WAL is a protocol

that ensures that in the event of a system crash, the recovery log contains sufficient information to perform the necessary UNDO and REDO work when a STEAL/NO-FORCE buffer management policy is used. The WAL protocol ensures that

1. All log records pertaining to an updated page are written to nonvolatile storage before the page itself is allowed to be overwritten in nonvolatile storage
2. A transaction is not considered to be committed until all of its log records (including its commit record) have been written to stable storage

The first point ensures that UNDO information required due to the STEAL policy will be present in the log in the event of a crash. Similarly, the second point ensures that any REDO information required due to the NO-FORCE policy will be present in the nonvolatile log. The WAL protocol is typically enforced with special support provided by the DBMS buffer manager.

12.3 Best Practices

12.3.1 Concurrency Control

12.3.1.1 Two-Phase Locking

The most prevalent implementation technique for concurrency control is locking. Typically, two types of locks are supported, *shared* (S) locks and *exclusive* (X) locks. The compatibility of these locks is defined by the *compatibility matrix* shown in Table 12.2. The compatibility matrix shows that two different transactions are allowed to hold S locks simultaneously on the same data item, but that X locks cannot be held on an item simultaneously with any other locks (by other transactions) on that item. S locks are used for protecting *read* access to data (i.e., multiple concurrent readers are allowed), and X locks are used for protecting *write* access to data. As long as a transaction is holding a lock, no other transaction is allowed to obtain a conflicting lock. If a transaction requests a lock that cannot be granted (due to a lock conflict), that transaction is *blocked* (i.e., prohibited from proceeding) until all the conflicting locks held by other transactions are released.

S and X locks as defined in Table 12.2 directly model the semantics of conflicts used in the definition of conflict serializability. Therefore, locking can be used to enforce serializability. Rather than testing for serializability after a schedule has been produced (as was done in the previous section), the blocking of transactions due to lock conflicts can be used to prevent nonserializable schedules from *ever* being produced.

A transaction is said to be *well formed* with respect to *reads* if it always holds an S or an X lock on an item while reading it, and well formed with respect to *writes* if it always holds an X lock on an item while writing it. Unfortunately, restricting all transactions to be well formed is not sufficient to guarantee serializability. For example, a nonserializable execution such as that of schedule 12.2 is still possible using well-formed transactions. Serializability can be enforced, however, through the use of *two-phase locking* (*2PL*). Two-phase locking requires that all transactions be well formed and that they respect the following rule: *Once a transaction has released a lock, it is not allowed to obtain any additional locks*. This rule results in transactions that have two phases:

1. A *growing phase* in which the transaction is acquiring locks
2. A *shrinking phase* in which locks are released

TABLE 12.2 Compatibility Matrix for S and X Locks

	S	X
S	*y*	*n*
X	*n*	*n*

The two-phase rule dictates that the transaction shifts from the growing phase to the shrinking phase at the instant it first releases a lock.

To see how 2PL enforces serializability, consider again schedule 12.2. Recall that the problem arises in this schedule because $w_0[A] \rightarrow r_1[A]$ but $r_1[B] \rightarrow w_0[B]$. This schedule could not be produced under 2PL, because transaction 1 (ReportSum) would be blocked when it attempted to read the value of A because transaction 0 would be holding an X lock on it. Transaction 0 would not be allowed to release this X lock before obtaining its X lock on B, and thus it would either abort or perform its update of B before transaction 1 is allowed to progress. In contrast, note that schedule 12.1 (the serial schedule) would be allowed in 2PL. 2PL would also allow the following (serializable) interleaved schedule:

$$r_1[A] \rightarrow r_0[A] \rightarrow r_1[B] \rightarrow c_1 \rightarrow w_0[A] \rightarrow r_0[B] \rightarrow w_0[B] \rightarrow c_0 \tag{12.4}$$

It is important to note, however, that 2PL is sufficient but not necessary for implementing serializability. In other words, there are schedules that are serializable but would not be allowed by 2PL. Schedule 12.3 is an example of such a schedule.

In order to implement 2PL, the DBMS contains a component called a *lock manager*. The lock manager is responsible for granting or blocking lock requests, for managing queues of blocked transactions, and for unblocking transactions when locks are released. In addition, the lock manager is also responsible for dealing with *deadlock* situations. A deadlock arises when a set of transactions is blocked, each waiting for another member of the set to release a lock. In a deadlock situation, none of the transactions involved can make progress. Database systems deal with deadlocks using one of two general techniques: avoidance or detection. Deadlock avoidance can be achieved by imposing an order in which locks can be obtained on data, by requiring transactions to predeclare their locking needs, or by aborting transactions rather than blocking them in certain situations.

Deadlock detection, on the other hand, can be implemented using *timeouts* or explicit checking. Timeouts are the simplest technique; if a transaction is blocked beyond a certain amount of time, it is assumed that a deadlock has occurred. The choice of a timeout interval can be problematic, however. If it is too short, then the system may infer the presence of a deadlock that does not truly exist. If it is too long, then deadlocks may go undetected for too long a time. Alternatively the system can explicitly check for deadlocks using a structure called a *waits-for graph*. A waits-for graph is a directed graph with a vertex for each active transaction. The lock manager constructs the graph by placing an edge from a transaction T_i to a transaction T_j $(i \neq j)$ if T_i is blocked waiting for a lock held by T_j. If the waits-for graph contains a cycle, all of the transactions involved in the cycle are waiting for each other, and thus they are deadlocked. When a deadlock is detected, one or more of the transactions involved is rolled back. When a transaction is rolled back, its locks are automatically released, so the deadlock will be broken.

12.3.1.2 Isolation Levels

As should be apparent from the previous discussion, transaction isolation comes at a cost in potential concurrency. Transaction blocking can add significantly to transaction response time.* As stated previously, serializability is typically implemented using 2PL, which requires locks to be held at least until all necessary locks have been obtained. Prolonging the holding time of locks increases the likelihood of blocking due to data contention.

In some applications, however, serializability is not strictly necessary. For example, a data analysis program that computes aggregates over large numbers of tuples may be able to tolerate some inconsistent access to the database in exchange for improved performance. The concept of *degrees of isolation* or *isolation levels* has been developed to allow transactions to trade concurrency for consistency in a controlled manner (Gray et al. 1975, Gray and Reuter 1993, Berenson et al. 1995). In their 1975 paper,

* Note that other, non-blocking approaches discussed later in this section also suffer from similar problems.

Gray et al. defined four degrees of consistency using characterizations based on locking, dependencies, and anomalies (i.e., results that could not arise in a serial schedule). The degrees were named degrees 0–3, with degree 0 being the least consistent and degree 3 intended to be equivalent to serializable execution.

The original presentation has served as the basis for understanding relaxed consistency in many current systems, but it has become apparent over time that the different characterizations in that paper were not specified to an equal degree of detail. In this section, we focus on the locking-based definitions of the isolation levels, as they are generally acknowledged to have "stood the test of time" (Berenson et al. 1995). However, the definition of the degrees of consistency requires an extension to the previous description of locking in order to address the *phantom problem*.

An example of the phantom problem is the following: assume a transaction T_i reads a set of tuples that satisfy a query predicate. A second transaction T_j inserts a new tuple that satisfies the predicate. If T_i then executes the query again, it will see the new item, so that its second answer differs from the first. This behavior could never occur in a serial schedule, as a "phantom" tuple appears in the midst of a transaction; thus, this execution is anomalous. The phantom problem is an artifact of the transaction model, consisting of reads and writes to *individual* data that we have used so far. In practice, transactions include *queries* that dynamically define sets based on predicates. When a query is executed, all of the tuples that satisfy the predicate at that time can be locked as they are accessed. Such individual locks, however, do not protect against the later addition of further tuples that satisfy the predicate.

One obvious solution to the phantom problem is to lock predicates instead of (or in addition to) individual items (Eswaran et al. 1976). This solution is impractical to implement, however, due to the complexity of detecting the overlap of a set of arbitrary predicates. Predicate locking can be approximated using techniques based on locking clusters of data or ranges of index values. Such techniques, however, are beyond the scope of this chapter. In this discussion, we will assume that predicates can be locked without specifying the technical details of how this can be accomplished (see Gray and Reuter (1993) and Mohan et al. (1992) for detailed treatments of this topic).

The locking-oriented definitions of the isolation levels are based on whether or not read and/or write operations are well formed (i.e., protected by the appropriate lock), and if so, whether those locks are *long duration* or *short duration*. Long-duration locks are held until the end of a transaction (i.e., when it commits or aborts); short-duration locks can be released earlier. Long-duration write locks on data items have important benefits for recovery, namely, they allow recovery to be performed using *before images*. If long-duration write locks are not used, then the following scenario could arise:

$$\mathrm{w}_0[\mathrm{A}] \rightarrow \mathrm{w}_1[\mathrm{A}] \rightarrow \mathrm{a}_0 \tag{12.5}$$

In this case, restoring A with T_0's before image of it will be incorrect because it would overwrite T_1's update. Simply ignoring the abort of T_0 is also incorrect. In that case, if T_1 were to subsequently abort, installing it before image would reinstate the value written by T_0. For this reason and for simplicity, locking systems typically hold long-duration locks on data items. This is sometimes referred to as *strict* locking (Bernstein et al. 1987).

Given these notions of locks, the degrees of isolation presented in the SQL-92 standard can be obtained using different lock protocols. In the following, all levels are assumed to be well formed with respect to writes and to hold long-duration *write* (i.e., exclusive) locks on updated data items. Four levels are defined (from weakest to strongest:)*

* It should be noted that two-phase locks can be substituted for the long-duration locks in these definitions without impacting the consistency provided. Long-duration locks are typically used, however, to avoid the recovery-related problems described previously.

`READ UNCOMMITTED`: This level, which provides the weakest consistency guarantees, allows transactions to read data that have been written by other transactions that have not committed. In a locking implementation, this level is achieved by being ill formed with respect to reads (i.e., not obtaining read locks). The risks of operating at this level include (in addition to the risks incurred at the more restrictive levels) the possibility of seeing updates that will eventually be rolled back and the possibility of seeing some of the updates made by another transaction but missing others made by that transaction.

`READ COMMITTED`: This level ensures that transactions only see updates that have been made by transactions that have committed. This level is achieved by being well formed with respect to reads on individual data items but holding the read locks only as short-duration locks. Transactions operating at this level run the risk of seeing *nonrepeatable* reads (in addition to the risks of the more restrictive levels). That is, a transaction T_0 could read a data item twice and see two different values. This anomaly could occur if a second transaction were to update the item and commit in between the two reads by T_0.

`REPEATABLE READ`: This level ensures that reads to individual data items are repeatable, but does not protect against the phantom problem described previously. This level is achieved by being well formed with respect to reads on individual data items, and holding those locks for long duration.

`SERIALIZABLE`: This level protects against all of the problems of the less restrictive levels, including the phantom problem. It is achieved by being well formed with respect to reads on *predicates* as well as on individual data items and holding all locks for long duration.

A key aspect of this definition of degrees of isolation is that as long as all transactions execute at the `READ UNCOMMITTED` level or higher, they are able to obtain at least the degree of isolation they desire without interference from any transactions running at lower degrees. Thus, these degrees of isolation provide a powerful tool that allows application writers or users to trade off consistency for improved concurrency. As stated earlier, the definition of these isolation levels for concurrency control methods that are not based on locking has been problematic. This issue is addressed in depth in Berenson et al. (1995).

It should be noted that the discussion of locking so far has ignored an important class of data that is typically present in databases, namely, *indexes*. Because indexes are auxiliary information, they can be accessed in a non-two-phase manner without sacrificing serializability. Furthermore, the hierarchical structure of many indexes (e.g., B-trees) makes them potential concurrency bottlenecks due to high contention at the upper levels of the structure. For this reason, significant effort has gone into developing methods for providing highly concurrent access to indexes. Pointers to some of this work can be found in the Further Information section at the end of this chapter.

12.3.1.3 Hierarchical Locking

The examples in the preceeding discussions of concurrency control primarily dealt with operations on a single granularity of data items (e.g., tuples). In practice, however, the notions of conflicts and locks can be applied at many different granularities. For example, it is possible to perform locking at the granularity of a page, a relation, or even an entire database. In choosing the proper granularity at which to perform locking, there is a fundamental tradeoff between potential concurrency and locking overhead. Locking at a fine granularity, such as an individual tuple, allows for maximum concurrency, as only transactions that are truly accessing the same tuple have the potential to conflict. The downside of such fine-grained locking, however, is that a transaction that accesses a large number of tuples will have to acquire a large number of locks. Each lock request requires a call to the lock manager. This overhead can be reduced by locking at a coarser granularity, but coarse granularity raises the potential for *false conflicts*. For example, two transactions that update different tuples residing on the same page would conflict under page-level locking but not under tuple-level locking.

The notion of hierarchical or multigranular locking was introduced to allow concurrent transactions to obtain locks at different granularities in order to optimize the above tradeoff (Gray et al. 1975).

TABLE 12.3 Compatibility Matrix for Regular and Intention Locks

	IS	IX	S	SIX	X
IS	*y*	*y*	*y*	*y*	*n*
IX	*y*	*y*	*n*	*n*	*n*
S	*y*	*n*	*y*	*n*	*n*
SIX	*y*	*n*	*n*	*n*	*n*
X	*n*	*n*	*n*	*n*	*n*

TABLE 12.4 Hierarchical Locking Rules

To Get	Must Have on All Ancestors
IS or S	IS or IX
IX, SIX, or X	IX or SIX

In hierarchical locking, a lock on a granule at a particular level of the granularity hierarchy implicitly locks all items included in that granule. For example, an S lock on a relation implicitly locks all pages and tuples in that relation. Thus, a transaction with such a lock can read any tuple in the relation without requesting additional locks. Hierarchical locking introduces additional lock modes beyond S and X. These additional modes allow transactions to declare their *intention* to perform an operation on objects at lower levels of the granularity hierarchy. The new modes are IS, IX, and SIX for *intention shared*, *intention exclusive*, and *shared with intention exclusive*, respectively. An IS (or IX) lock on a granule provides no privileges on that granule, but indicates that the holder intends to obtain S (or X) lock on one or more finer granules. An SIX lock combines an S lock on the entire granule with an IX lock. SIX locks support the common access pattern of scanning the items in a granule (e.g., tuples in a relation) and choosing to update a fraction of them based on their values.

Similarly to S and X locks, these lock modes can be described using a compatibility matrix. The compatibility matrix for these modes is shown in Table 12.3. In order for transactions locking at different granularities to coexist, all transactions must follow the same hierarchical locking protocol starting from the root of the granularity hierarchy. This protocol is shown in Table 12.4. For example, to read a single record, a transaction would obtain IS locks on the database, relation, and page, followed by an S lock on the specific tuple. If a transaction wanted to read all or most tuples on a page, then it could obtain IS locks on the database and relation, followed by an S lock on the entire page. By following this uniform protocol, potential conflicts between transactions that ultimately obtain S and/or X locks at different granularities can be detected.

A useful extension to hierarchical locking is known as *lock escalation*. Lock escalation allows the DBMS to automatically adjust the granularity at which transactions obtain locks, based on their behavior. If the system detects that a transaction is obtaining locks on a large percentage of the granules that make up a larger granule, it can attempt to grant the transaction a lock on the larger granule so that no additional locks will be required for subsequent accesses to other objects in that granule. Automatic escalation is useful because the access pattern that a transaction will produce is often not known until run time.

12.3.1.4 Other Concurrency Control Methods

As stated previously, 2PL is the most generally accepted technique for ensuring serializability. Locking is considered to be a *pessimistic* technique because it is based on the assumption that transactions are likely to interfere with each other and takes measures (e.g., blocking) to ensure that such interference does not occur. An important alternative to locking is *optimistic concurrency control*. Optimistic methods (e.g., Kung and Robinson 1981) allow transactions to perform their operations without obtaining any locks. To ensure that concurrent executions do not violate serializability, transactions must perform

a *validation phase* before they are allowed to commit. Many optimistic protocols have been proposed. In the algorithm of Kung and Robinson (1981), the validation process ensures that the reads and writes performed by a validating transaction did not conflict with any other transactions with which it ran concurrently. If during validation it is determined a conflict had occurred, the validating transaction is aborted and restarted.

Unlike locking, which depends on *blocking* transactions to ensure isolation, optimistic policies depend on transaction *restart*. As a result, although they do not perform any blocking, the performance of optimistic policies can be hurt by data contention (as are pessimistic schemes)—a high degree of data contention will result in a large number of unsuccessful transaction executions. The performance tradeoffs between optimistic and pessimistic have been addressed in numerous studies (see Agrawal et al. 1987). In general, locking is likely to be superior in resource-limited environments because blocking does not consume CPU or disk resources. In contrast, optimistic techniques may have performance advantages in situations where resources are abundant, because they allow more executions to proceed concurrently. If resources are abundant, then the resource consumption of restarted transactions will not significantly hurt performance. In practice, however, resources are typically limited, and thus concurrency control in most commercial database systems is based on locking.

Another class of concurrency control techniques is known as *multiversion concurrency control* (e.g., Reed 1983). As updating transactions modify data items, these techniques retain the previous versions of the items online. Read-only transactions (i.e., transactions that perform no updates) can then be provided with access to these older versions, allowing them to see a consistent (although possibly somewhat out-of-date) snapshot of the database. Optimistic, multiversion, and other concurrency control techniques (e.g., timestamping) are addressed in further detail in Bernstein et al. (1987).

12.3.2 Recovery

The recovery subsystem is generally considered to be one of the more difficult parts of a DBMS to design for two reasons: First, recovery is required to function in failure situations and must correctly cope with a huge number of possible system and database states. Second, the recovery system depends on the behavior of many other components of the DBMS, such as concurrency control, buffer management, disk management, and query processing. As a result, few recovery methods have been described in the literature in detail. One exception is the ARIES recovery system developed at IBM (Mohan et al. 1992). Many details about the ARIES method have been published, and the method has been included in a number of DBMSs. Furthermore, the ARIES method involves only a small number of basic concepts. For these reasons, we focus on the ARIES method in the remainder of this section. The ARIES method is related to many other recovery methods such as those described in Bernstein et al. (1987) and Gray and Reuter (1993). A comparison with other techniques appears in Mohan et al. (1992).

12.3.2.1 Overview of ARIES

ARIES is a refinement of the WAL protocol. Recall that the WAL protocol enables the use of a STEAL/NO-FORCE buffer management policy, which means that pages on stable storage can be overwritten at any time and that data pages do not need to be forced to disk in order to commit a transaction. As with other WAL implementations, each page in the database contains an LSN, which uniquely identifies the log record for the latest update that was applied to the page. This LSN (referred to as the *pageLSN*) is used during recovery to determine whether or not an update for a page must be redone. LSN information is also used to determine the point in the log from which the REDO pass must commence during restart from a system crash. LSNs are often implemented using the physical address of the log record in the log to enable the efficient location of a log record given its LSN.

Much of the power and relative simplicity of the ARIES algorithm is due to its REDO paradigm of *repeating history*, in which it redoes updates for *all* transactions—including those that will eventually be undone. Repeating history enables ARIES to employ a variant of the *physiological logging* technique described

earlier: it uses *page-oriented REDO* and a form of *logical UNDO*. Page-oriented REDO means that REDO operations involve only a single page and that the affected page is specified in the log record. This is part of physiological logging. In the context of ARIES, logical UNDO means that the operations performed to undo an update do not need to be the exact inverses of the operations of the original update.

In ARIES, logical UNDO is used to support fine-grained (i.e., tuple-level) locking and high-concurrency index management. For an example of the latter issue, consider a case in which a transaction T1 updates an index entry on a given page P1. Before T1 completes, a second transaction T2 could split P1, causing the index entry to be moved to a new page (P2). If T1 must be undone, a physical, page-oriented approach would fail because it would erroneously attempt to perform the UNDO operation on P1. Logical UNDO solves this problem by using the index structure to find the index entry, and then applying the UNDO operation to it in its new location. In contrast to UNDO, page-oriented REDO can be used because the repeating history paradigm ensures that REDO operations will always find the index entry on the page referenced in the log record—any operations that had affected the location of the index operation at the time the log record was created will be replayed before that log record is redone.

ARIES uses a three-pass algorithm for restart recovery. The first pass is the *analysis* pass, which processes the log forward from the most recent checkpoint. This pass determines information about dirty pages and active transactions that is used in the subsequent passes. The second pass is the *REDO* pass, in which history is repeated by processing the log forward from the earliest log record that could require REDO, thus ensuring that all logged operations have been applied. The third pass is the *UNDO* pass. This pass proceeds backward from the end of the log, removing from the database the effects of all transactions that had not committed at the time of the crash. These passes are shown in Figure 12.2. (Note that the relative ordering of the starting point for the REDO pass, the endpoint for the UNDO pass, and the checkpoint can be different than that shown in the figure.) The three passes are described in more detail in the subsequent sections.

ARIES maintains two important data structures during normal operation. The first is the *transaction table*, which contains status information for each transaction that is currently running. This information includes a field called the *lastLSN*, which is the LSN of the most recent log record written by the transaction. The second data structure, called the *dirty-page table*, contains an entry for each "dirty" page. A page is considered to be dirty if it contains updates that are not reflected on stable storage. Each entry in the dirty-page table includes a field called the *recoveryLSN*, which is the LSN of the log record that caused the associated page to become dirty. Therefore, the *recoveryLSN* is the LSN of the earliest log record that might need to be redone for the page during restart. Log records belonging to the same transaction are linked backward in time using a field in each log record called the *prevLSN* field. When a new log record is written for a transaction, the value of the *lastLSN* field in the transaction-table entry is placed in the *prevLSN* field of the new record and the new record's LSN is entered as the *lastLSN* in the transaction-table entry.

During normal operation, checkpoints are taken periodically. ARIES uses a form of fuzzy checkpoints which are extremely inexpensive. When a checkpoint is taken, a checkpoint record is constructed which includes the contents of the transaction table and the dirty-page table. Checkpoints are efficient, since no operations need be quiesced and no database pages are flushed to perform a checkpoint. However, the effectiveness of checkpoints in reducing the amount of the log that must be maintained is limited in

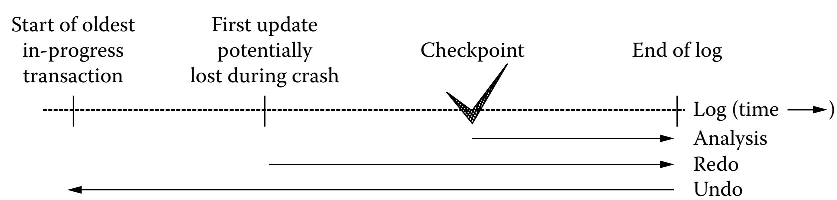

FIGURE 12.2 The three passes of ARIES restart.

part by the earliest *recoveryLSN* of the dirty pages at checkpoint time. Therefore, it is helpful to have a background process that periodically writes dirty pages to nonvolatile storage.

12.3.2.2 Analysis

The job of the analysis pass of restart recovery is threefold: (1) it determines the point in the log at which to start the REDO pass, (2) it determines which pages could have been dirty at the time of the crash in order to avoid unnecessary I/O during the REDO pass, and (3) it determines which transactions had not committed at the time of the crash and will therefore need to be undone.

The analysis pass begins at the most recent checkpoint and scans forward to the end of the log. It reconstructs the transaction table and dirty-page table to determine the state of the system as of the time of the crash. It begins with the copies of those structures that were logged in the checkpoint record. Then, the contents of the tables are modified according to the log records that are encountered during the forward scan. When a log record for a transaction that does not appear in the transaction table is encountered, that transaction is added to the table. When a log record for the commit or the abort of a transaction is encountered, the corresponding transaction is removed from the transaction table. When a log record for an update to a page that is not in the dirty-page table is encountered, that page is added to the dirty-page table, and the LSN of the record which caused the page to be entered into the table is recorded as the *recoveryLSN* for that page. At the end of the analysis pass, the dirty-page table is a conservative (since some pages may have been flushed to nonvolatile storage) list of all database pages that could have been dirty at the time of the crash, and the transaction table contains entries for those transactions that will actually require undo processing during the UNDO phase. The earliest *recoveryLSN* of all the entries in the dirty-page table, called the *firstLSN*, is used as the spot in the log from which to begin the REDO phase.

12.3.2.2.1 REDO

As stated earlier, ARIES employs a redo paradigm called *repeating history*. That is, it redoes updates for *all* transactions, committed or otherwise. The effect of repeating history is that at the end of the REDO pass, the database is in the same state with respect to the logged updates that it was in at the time that the crash occurred. The REDO pass begins at the log record whose LSN is the *firstLSN* determined by analysis and scans forward from there. To redo an update, the logged action is reapplied and the *pageLSN* on the page is set to the LSN of the redone log record. No logging is performed as the result of a redo. For each log record, the following algorithm is used to determine if the logged update must be redone:

- If the affected page is not in the dirty-page table, then the update does *not* require redo.
- If the affected page is in the dirty-page table, but the *recoveryLSN* in the page's table entry is *greater than* the LSN of the record being checked, then the update does *not* require redo.
- Otherwise, the LSN stored on the page (the *pageLSN)* must be checked. This may require that the page be read in from disk. If the *pageLSN* is *greater than or equal to* the LSN of the record being checked, then the update does *not* require redo. Otherwise, the update *must* be redone.

12.3.2.2.2 UNDO

The UNDO pass scans backwards from the end of the log. During the UNDO pass, all transactions that had not committed by the time of the crash must be undone. In ARIES, undo is an *unconditional* operation. That is, the *pageLSN* of an affected page is not checked, because it is always the case that the undo must be performed. This is due to the fact that the *repeating of history* in the REDO pass ensures that all logged updates have been applied to the page.

When an update is undone, the undo operation is applied to the page and is logged using a special type of log record called a *compensation log record* (CLR). In addition to the undo information, a CLR contains a field called the *UndoNxtLSN*. The *UndoNxtLSN* is the LSN of the next log record that must be undone for the transaction. It is set to the value of the *prevLSN* field of the log record being undone. The logging of CLRs in this fashion enables ARIES to avoid ever having to undo the effects of an undo

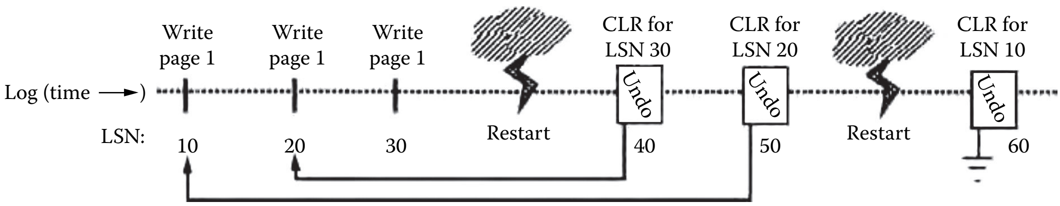

FIGURE 12.3 The use of CLRs for UNDO.

(e.g., as the result of a system crash during an abort), thereby limiting the amount of work that must be undone and bounding the amount of logging done in the event of multiple crashes. When a CLR is encountered during the backward scan, no operation is performed on the page, and the backward scan continues at the log record referenced by the *UndoNxtLSN* field of the CLR, thereby jumping over the undone update and all other updates for the transaction that have already been undone (the case of multiple transactions will be discussed shortly). An example execution is shown in Figure 12.3.

In Figure 12.3, a transaction logged three updates (LSNs 10, 20, and 30) before the system crashed for the first time. During REDO, the database was brought up to date with respect to the log (i.e., 10, 20, and/or 30 were redone if they were not on nonvolatile storage), but since the transaction was in progress at the time of the crash, they must be undone. During the UNDO pass, update 30 was undone, resulting in the writing of a CLR with LSN 40, which contains an *UndoNxtLSN* value that points to 20. Then, 20 was undone, resulting in the writing of a CLR (LSN 50) with an *UndoNxtLSN* value that points to 10. However, the system then crashed for a second time before 10 was undone. Once again, history is repeated during REDO, which brings the database back to the state it was in after the application of LSN 50 (the CLR for 20). When UNDO begins during this second restart, it will first examine the log record 50. Since the record is a CLR, no modification will be performed on the page, and UNDO will skip to the record whose LSN is stored in the *UndoNxtLSN* field of the CLR (i.e., LSN 10). Therefore, it will continue by undoing the update whose log record has LSN 10. This is where the UNDO pass was interrupted at the time of the second crash. Note that no extra logging was performed as a result of the second crash.

In order to undo multiple transactions, restart UNDO keeps a list containing the next LSN to be undone for each transaction being undone. When a log record is processed during UNDO, the *prevLSN* (or *UndoNxtLSN*, in the case of a CLR) is entered as the next LSN to be undone for that transaction. Then the UNDO pass moves on to the log record whose LSN is the most recent of the next LSNs to be redone. UNDO continues backward in the log until all of the transactions in the list have been undone up to and including their first log record. UNDO for *transaction rollback* works similarly to the UNDO pass of the restart algorithm as described above. The only difference is that during transaction rollback, only a single transaction (or part of a transaction) must be undone. Therefore, rather than keeping a list of LSNs to be undone for multiple transactions, rollback can simply follow the backward chain of log records for the transaction to be rolled back.

12.4 Research Issues and Summary

The model of ACID transactions that has been described in this chapter has proven to be quite durable in its own right, and serves as the underpinning for the current generation of database and transaction processing systems. This chapter has focused on the issues of concurrency control and recovery in a centralized environment. It is important to note, however, that the basic model is used in many types of distributed and parallel DBMS environments and the mechanisms described here have been successfully adapted for use in these more complex systems. Additional techniques, however, are needed in such environments. One important technique is *two-phase commit*, which is a protocol for ensuring that all participants in a distributed transaction agree on the decision to commit or abort that transaction.

While the basic transaction model has been a clear success, its limitations have also been apparent for quite some time (e.g., Gray 1981). Much of the ongoing research related to concurrency control and recovery is aimed at addressing some of these limitations. This research includes the development of new implementation techniques, as well as the investigation of new and extended transaction models.

The ACID transaction model suffers from a lack of flexibility and the inability to model many types of interactions that arise in complex systems and organizations. For example, in collaborative work environments, strict isolation is not possible or even desirable (Korth 1995). Workflow management systems are another example where the ACID model, which works best for relatively simple and short transactions, is not directly appropriate. For these types of applications, a richer, multilevel notion of transactions is required.

In addition to the problems raised by complex application environments, there are also many computing environments for which the ACID model is not fully appropriate. These include environments such as mobile wireless networks, where large periods of disconnection are possible, and loosely coupled wide-area networks (the Internet as an extreme example) in which the availability of systems could be low. The techniques that have been developed for supporting ACID transactions must be adjusted to cope with such highly variable situations. New techniques must also be developed to provide concurrency control and recovery in nontraditional environments such as heterogeneous systems and dissemination-oriented environments.

A final limitation of ACID transactions in their simplest form is that they are a general mechanism, and hence, do not exploit the semantics of data and/or applications. Such knowledge could be used to significantly improve system performance. Therefore, the development of concurrency control and recovery techniques that can exploit application-specific properties is another area of active research.

As should be obvious from the preceding discussion, there is still a significant amount of work that remains to be done in the areas of concurrency control and recovery for database systems. The basic concepts, however, such as serializability theory, 2PL, and WAL, will continue to be a fundamental technology, both in their own right and as building blocks for the development of more sophisticated and flexible information systems.

Glossary

Abort: The process of rolling back an uncommitted transaction. All changes to the database state made by that transaction are removed.

ACID properties: The transaction properties of atomicity, consistency, isolation, and durability that are upheld by the DBMS.

Checkpointing: An action taken during normal system operation that can help limit the amount of recovery work required in the event of a system crash.

Commit: The process of successfully completing a transaction. Upon commit, all changes to the database state made by a transaction are made permanent and visible to other transactions.

Concurrency control: The mechanism that ensures that individual users see consistent states of the database even though operations on behalf of many users may be interleaved by the database system.

Concurrent execution: The (possibly) interleaved execution of multiple transactions simultaneously.

Conflicting operations: Two operations are said to conflict if they both operate on the same data item and at least one of them is a *write*().

Deadlock: A situation in which a set of transactions is blocked, each waiting for another member of the set to release a lock. In such a case, none of the transactions involved can make progress.

Log: A sequential file that stores information about transactions and the state of the system at certain instances.

Log record: An entry in the log. One or more log records are written for each update performed by a transaction.

LSN: A number assigned to a log record, which serves to uniquely identify that record in the log. LSNs are typically assigned in a monotonically increasing fashion so that they provide an indication of relative position.

Multiversion concurrency control: A concurrency control technique that provides read-only transactions with conflict-free access to previous versions of data items.

Nonvolatile storage: Storage, such as magnetic disks or tapes, whose contents persist across power failures and system crashes.

Optimistic concurrency control: A concurrency control technique that allows transactions to proceed without obtaining locks and ensures correctness by validating transactions upon their completion.

Recovery: The mechanism that ensures that the database is fault-tolerant, that is, the database state is not corrupted as the result of a software, system, or media failure.

Schedule: A schedule for a set of transaction executions is a partial ordering of the operations performed by those transactions, which shows how the operations are interleaved.

Serial execution: The execution of a single transaction at a time.

Serializability: The property that an (possibly interleaved) execution of a group transactions has the same effect on the database, and produces the same output, as some serial (i.e., noninterleaved) execution of those transactions.

STEAL/NO-FORCE: A buffer management policy that allows committed data values to be overwritten on nonvolatile storage and does not require committed values to be written to nonvolatile storage. This policy provides flexibility for the buffer manager at the cost of increased demands on the recovery subsystem.

Transaction: A unit of work, possibly consisting of multiple data accesses and updates, that must commit or abort as a single atomic unit. Transactions have the ACID properties of *atomicity, consistency, isolation*, and *durability*.

Two-phase locking (2PL): A locking protocol that is a sufficient but not a necessary condition for serializability. Two-phase locking requires that all transactions be well formed and that once a transaction has released a lock, it is not allowed to obtain any additional locks.

Volatile storage: Storage, such as main memory, whose state is lost in the event of a system crash or power outage.

Well formed: A transaction is said to be well formed with respect to reads if it always holds a shared or an exclusive lock on an item while reading it, and well formed with respect to writes if it always holds an exclusive lock on an item while writing it.

Write-ahead logging: A protocol that ensures all log records required to correctly perform recovery in the event of a crash are placed on nonvolatile storage.

Conf. on Management of Data (SIGMOD'92)*, San Diego, CA, June 1992. © 1992 by the Association for Computing Machinery, Inc. (ACM).

Further Information

For many years, what knowledge that existed in the public domain about concurrency control and recovery was passed on primarily though the use of multiple-generation copies of a set of lecture notes written by Jim Gray in the late seventies ("Notes on Database Operating Systems" in *Operating Systems: An Advanced Course* published by Springer–Verlag, Berlin, Germany, 1978). Fortunately, this state of affairs has been supplanted by the publication of *Transaction Processing: Concepts and Techniques* by

Jim Gray and Andreas Reuter (Morgan Kaufmann, San Mateo, CA, 1993). This latter book contains a detailed treatment of all of the topics covered in this chapter, plus many others that are crucial for implementing transaction processing systems.

An excellent treatment of concurrency control and recovery theory and algorithms can be found in *Concurrency Control and Recovery in Database Systems* by Phil Bernstein, Vassos Hadzilacos, and Nathan Goodman (Addison–Wesley, Reading, MA, 1987). Another source of valuable information on concurrency control and recovery implementation is the series of papers on the ARIES method by C. Mohan and others at IBM, some of which are referenced in this chapter. The book *The Theory of Database Concurrency Control* by Christos Papadimitriou (Computer Science Press, Rockville, MD, 1986) covers a number of serializability models.

The performance aspects of concurrency control and recovery techniques have been only briefly addressed in this chapter. More information can be found in the recent books *Performance of Concurrency Control Mechanisms in Centralized Database Systems* edited by Vijay Kumar (Prentice Hall, Englewood Cliffs, NJ, 1996) and *Recovery in Database Management Systems*, edited by Vijay Kumar and Meichun Hsu (Prentice Hall, Englewood Cliffs, NJ, in press). Also, the performance aspects of transactions are addressed in *The Benchmark Handbook: For Database and Transaction Processing Systems* (2nd ed.), edited by Jim Gray (Morgan Kaufmann, San Mateo, CA, 1993).

Finally, extensions to the ACID transaction model are discussed in *Database Transaction Models*, edited by Ahmed Elmagarmid (Morgan Kaufmann, San Mateo, CA, 1993). Papers containing the most recent work on related topics appear regularly in the ACM SIGMOD Conference and the International Conference on Very Large Databases (VLDB), among others.

Distributed and Parallel Database Systems

13.1 Introduction

The maturation of database management system (DBMS) technology [1] has coincided with significant developments in distributed computing and parallel processing technologies. The end result is the development of *distributed DBMSs* and *parallel DBMSs* that are now the dominant data management tools for highly data-intensive applications. With the emergence of cloud computing, distributed and parallel database systems have started to converge.

A parallel computer, or multiprocessor, is itself a distributed system made of a number of nodes (with processors, memories, and disks) connected by a high-speed network within a cabinet. Distributed database technology can be naturally extended to implement *parallel database systems*, that is, database systems on parallel computers [2,3]. Parallel database systems exploit the parallelism in data management in order to deliver high-performance and high-availability database servers.

In this chapter, we present an overview of the distributed DBMS and parallel DBMS technologies, highlight the unique characteristics of each, and indicate the similarities between them. We also discuss the new challenges and emerging solutions.

13.2 Underlying Principles

The fundamental principle behind data management is data independence, which enables applications and users to share data at a high conceptual level while ignoring implementation details. This principle has been achieved by database systems that provide advanced capabilities such as schema management, high-level query languages, access control, automatic query processing and optimization, transactions, and data structures for supporting complex objects.

A distributed database [1] is a collection of multiple, logically interrelated databases distributed over a computer network. A distributed database system is defined as the software system that permits

the management of the distributed database and makes the distribution transparent to the users. Distribution transparency extends the principle of data independence so that distribution is not visible to users.

These definitions assume that each site logically consists of a single, independent computer. Therefore, each site has the capability to execute applications on its own. The sites are interconnected by a computer network with loose connection between sites that operate independently. Applications can then issue queries and transactions to the distributed database system that transforms them into local queries and local transactions and integrates the results.

The database is physically distributed across the data sites by fragmenting and replicating the data. Given a relational database schema, for instance, fragmentation subdivides each relation into partitions based on some function applied to some tuples' attributes. Based on the user access patterns, each of the fragments may also be replicated to improve locality of reference (and thus performance) and availability. The use of a set-oriented data model (like relational) has been crucial to define fragmentation, based on data subsets.

The functions provided by a distributed database system could be those of a database system (schema management, access control, query processing, transaction support, etc.). But since they must deal with distribution, they are more complex to implement. Therefore, many systems support only a subset of these functions. When the data and the databases already exist, one is faced with the problem of providing integrated access to heterogeneous data. This process is known as *data integration*, which consists of defining a global schema over the existing data and mappings between the global schema and the local database schemas. Data integration systems have received, over time, several other names such as federated database systems, multidatabase systems (MDBMS), and mediator systems. Standard protocols such as Open Database Connectivity (ODBC) and Java Database Connectivity (JDBC) ease data integration using standard query language (SQL). In the context of the web, mediator systems allow general access to autonomous data sources (such as files, databases, and documents) in read-only mode. Thus, they typically do not support all database functions such as transactions and replication.

When the architectural assumption of each site being a (logically) single, independent computer is relaxed, one gets a parallel database system, that is, a database system implemented on a tightly coupled multiprocessor or a cluster. The main difference with a distributed database system is that there is a single operating system which facilitates implementation, and the network is typically faster and more reliable. The objective of parallel database systems is high performance and high availability. High performance (i.e., improving transaction throughput or query response time) is obtained by exploiting data partitioning and query parallelism, while high availability is obtained by exploiting replication. Again, this has been made possible by the use of a set-oriented data model, which eases parallelism—in particular, independent parallelism between data subsets.

There are three forms of parallelism inherent in data-intensive application workloads. *Inter-query parallelism* enables the parallel execution of multiple queries generated by concurrent transactions. *Intra-query parallelism* makes the parallel execution of multiple, independent operations (e.g., select operations) possible within the same query. Both inter-query and intra-query parallelism can be obtained by using *data partitioning*, which is similar to horizontal fragmentation. Finally, with *intra-operation parallelism*, the same operation can be executed as many sub-operations using *function partitioning* in addition to data partitioning. The set-oriented mode of database languages (e.g., SQL) provides many opportunities for intra-operation parallelism.

In a distributed or parallel environment, it should be easier to accommodate increasing database sizes or increasing performance demands. Major system overhauls are seldom necessary; expansion can usually be handled by adding more processing and storage power to the system.

Ideally, a parallel DBMS (and to a lesser degree a distributed DBMS) should demonstrate two advantages: *linear scaleup* and *linear speedup*. Linear scaleup refers to a sustained performance for a linear increase in both database size and processing and storage power. Linear speedup refers to a linear increase

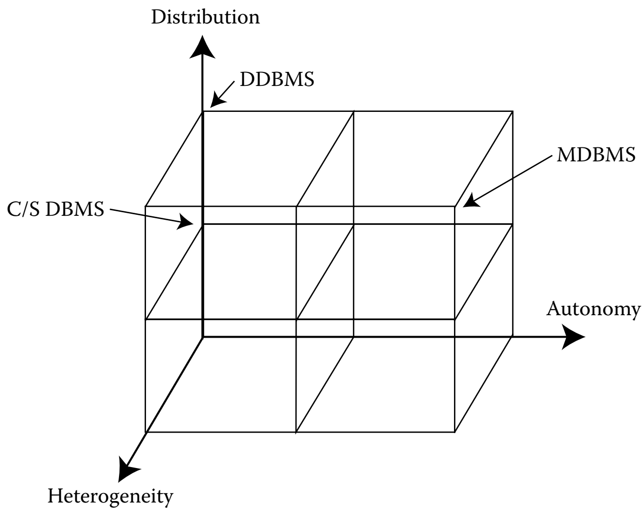

FIGURE 13.1 Distributed DBMS architectures. (Adapted from Özsu, T.M. and Valduriez, P., *Principles of Distributed Database Systems*, 3rd edn., Springer, 2011.)

in performance for a constant database size and a linear increase in processing and storage power. Furthermore, extending the system should require minimal reorganization of the existing database.

There are a number of possible ways in which a distributed DBMS may be architected. We use a classification (Figure 13.1) that organizes the systems as characterized with respect to three dimensions: (1) the autonomy of local systems, (2) their distribution, and (3) their heterogeneity. Autonomy, in this context, refers to the distribution of control, not of data. It indicates the degree to which individual DBMSs can operate independently. Whereas autonomy refers to the distribution (or decentralization) of control, the distribution dimension of the taxonomy deals with the physical distribution of data over multiple sites (or nodes in a parallel system). There are a number of ways DBMSs have been distributed. We distinguish between client/server (C/S) distribution and peer-to-peer (P2P) distribution (or full distribution). With C/S DBMS, sites may be clients or servers, thus with different functionality, whereas with homogeneous P2P DBMS (DDBMS in Figure 13.1), all sites provide the same functionality. Note that DDBMS came before C/S DBMS in the late 1970s. P2P data management struck back in the 2000 with modern variations to deal with very-large-scale autonomy and decentralized control. Heterogeneity refers to data models, query languages, and transaction management protocols. MDBMS deal with heterogeneity, in addition to autonomy and distribution.

13.3 Distributed and Parallel Database Technology

Distributed and parallel DBMSs provide the same functionality as centralized DBMSs except in an environment where data are distributed across the sites on a computer network or across the nodes of a parallel system. As discussed earlier, the users are unaware of data distribution. Thus, these systems provide the users with a *logically integrated* view of the *physically distributed* database. Maintaining this view places significant challenges on system functions. We provide an overview of these new challenges in this section. We assume familiarity with basic database management techniques.

13.3.1 Query Processing and Optimization

Query processing is the process by which a declarative query is translated into low-level data manipulation operations. SQL is the standard query language that is supported in current DBMSs.

Query optimization refers to the process by which the "best" execution strategy for a given query is found from among a set of alternatives.

In centralized DBMSs, the process typically involves two steps [1]: *query decomposition* and *query optimization*. Query decomposition takes an SQL query and translates it into one expressed in relational algebra. In the process, the query is analyzed semantically so that incorrect queries are detected and rejected as easily as possible, and correct queries are simplified. Simplification involves the elimination of redundant predicates, which may be introduced as a result of query modification to deal with views, security enforcement, and semantic integrity control. The simplified query is then restructured as an algebraic query.

For a given SQL query, there are usually more than one possible algebraic equivalents. Some of these algebraic queries are "better" than others. The quality of an algebraic query is defined in terms of expected performance. The traditional procedure is to obtain an initial algebraic query by translating the predicates and the target statement into relational operations as they appear in the query. This initial algebraic query is then transformed, using algebraic transformation rules, into other algebraic queries until the "best" one is found.* The query optimizer is usually seen as three components: a search space, a cost model, and a search strategy. The *search space* is the set of alternative execution plans to represent the input query. These plans are equivalent, in the sense that they yield the same result but they differ on the execution order of operations and the way these operations are implemented. The *cost model* predicts the cost of a given execution plan. To be accurate, the cost model must have accurate knowledge about the parallel execution environment. The *search strategy* explores the search space and selects the best plan. It defines which plans are examined and in which order.

In distributed DBMSs, two additional steps are involved between query decomposition and query optimization: *data localization* and *global query optimization* [1].

The input to data localization is the initial algebraic query generated by the query decomposition step. The initial algebraic query is specified on global relations irrespective of their fragmentation or distribution. The main role of data localization is to localize the query's data using data distribution information. In this step, the fragments that are involved in the query are determined, and the query is transformed into one that operates on fragments rather than on global relations. As indicated earlier, fragmentation is defined through fragmentation rules that can be expressed as relational operations (horizontal fragmentation by selection, vertical fragmentation by projection). A distributed relation can be reconstructed by applying the inverse of the fragmentation rules. This is called a *localization program*. The localization program for a horizontally (vertically) fragmented query is the union (join) of the fragments. Thus, during the data localization step, each global relation is first replaced by its localization program, and then the resulting fragment query is simplified and restructured to produce another "good" query. Simplification and restructuring may be done according to the same rules used in the decomposition step. As in the decomposition step, the final fragment query is generally far from optimal; the process has only eliminated "bad" algebraic queries.

The input to global query optimization step is a fragment query, that is, an algebraic query on fragments. The goal of global query optimization is to find an execution strategy for the query which is close to optimal. Remember that finding the optimal solution is computationally intractable. An execution strategy for a distributed query can be described with *relational algebra operations* and *communication primitives* (send/receive operations) for transferring data between sites. The previous layers have already performed some optimizations—for example, by eliminating redundant expressions. However, this optimization is independent of fragment characteristics such as cardinalities. In addition, communication operations are not yet specified. By permuting the ordering of operations within one fragment query, many equivalent query execution plans may be found.

* The difference between an optimal plan and the best plan is that the optimizer does not, because of computational intractability, examine all of the possible plans.

In a distributed environment, the cost function, often defined in terms of time units, refers to computing resources such as disk space, disk I/Os, buffer space, central processing unit (CPU) cost, and communication cost. Generally, it is a weighted combination of I/O, CPU, and communication costs. To select the ordering of operations, it is necessary to predict execution costs of alternative candidate orderings. Determining execution costs before query execution (i.e., static optimization) is based on fragment statistics and the formulas for estimating the cardinalities of results of relational operations. Thus the optimization decisions depend on the available statistics on fragments. An important aspect of query optimization is *join ordering*, since permutations of the joins within the query may lead to improvements of several orders of magnitude. One basic technique for optimizing a sequence of distributed join operations is through the use of the semijoin operator. The main value of the semijoin in a distributed system is to reduce the size of the join operands and thus the communication cost. However, more recent techniques, which consider local processing costs as well as communication costs, do not use semijoins because they might increase local processing costs. The output of the query optimization layer is an optimized algebraic query with communication operations included on fragments.

Parallel query optimization exhibits similarities with distributed query processing [4,5]. It takes advantage of both intra-operation parallelism, which was discussed earlier, and inter-operation parallelism.

Intra-operation parallelism is achieved by executing an operation on several nodes of a multiprocessor machine. This requires that the operands have been previously partitioned, that is, horizontally fragmented, across the nodes [6]. The way in which a base relation is partitioned is a matter of physical design. Typically, partitioning is performed by applying a hash function on an attribute of the relation, which will often be the join attribute. The set of nodes where a relation is stored is called its *home*. The *home of an operation* is the set of nodes where it is executed. The home of an operation must also be the home of its operand relations in order for the operation to access its operands. For binary operations such as join, this might imply repartitioning one of the operands [7]. The optimizer might even sometimes find that repartitioning both operands is useful. Parallel optimization to exploit intra-operation parallelism can make use of some of the techniques devised for distributed databases.

Inter-operation parallelism occurs when two or more operations are executed in parallel, either as a dataflow or independently. We designate as *dataflow* the form of parallelism induced by *pipelining*. *Independent* parallelism occurs when operations are executed at the same time or in an arbitrary order. Independent parallelism is possible only when the operations do not involve the same data.

13.3.2 Concurrency Control

Whenever multiple users access (read and write) a shared database, these accesses need to be synchronized to ensure database consistency. The synchronization is achieved by means of *concurrency control algorithms*, which enforce a correctness criterion such as *serializability*. User accesses are encapsulated as *transactions* [8], whose operations at the lowest level are a set of read and write operations to the database. Transactions typically have four properties: *atomicity*, *consistency*, *isolation*, and *durability*, which are collectively known as *ACID properties*. Concurrency control algorithms enforce the *isolation* property of transaction execution, which states that the effects of one transaction on the database are isolated from other transactions until the first completes its execution.

The most popular concurrency control algorithms are *locking*-based. In such schemes, a lock, in either shared or exclusive mode, is placed on some unit of storage (usually a page) whenever a transaction attempts to access it. These locks are placed according to lock compatibility rules such that *read–write*, *write–read*, and *write–write* conflicts are avoided. It is a well-known theorem that if lock actions on behalf of concurrent transactions obey the following simple rule, then it is possible to ensure the serializability of these transactions: "No lock on behalf of a transaction should be set once a lock previously held by the transaction is released." This is known as *two-phase locking* [9], since transactions go through a growing phase when they obtain locks and a shrinking phase when they release locks.

In general, releasing of locks prior to the end of a transaction is problematic. Thus, most of the locking-based concurrency control algorithms are *strict* in that they hold on to their locks until the end of the transaction.

In distributed DBMSs, the challenge is to extend both the serializability argument and the concurrency control algorithms to the distributed execution environment. In these systems, the operations of a given transaction may execute at multiple sites where they access data. In such a case, the serializability argument is more difficult to specify and enforce. The complication is due to the fact that the serialization order of the same set of transactions may be different at different sites. Therefore, the execution of a set of distributed transactions is serializable if and only if

1. The execution of the set of transactions at each site is serializable.
2. The serialization orders of these transactions at all these sites are identical.

Distributed concurrency control algorithms enforce this notion of *global serializability*. In locking-based algorithms, there are three alternative ways of enforcing global serializability: centralized locking, primary copy locking, and distributed locking.

In *centralized locking*, there is a single lock table for the entire distributed database. This lock table is placed under the control of a single lock manager at one of the sites. The lock manager is responsible for setting and releasing locks on behalf of transactions. Since all locks are managed at one site, this is similar to centralized concurrency control, and it is straightforward to enforce the global serializability rule. These algorithms are simple to implement, but suffer from two problems. The central site may become a bottleneck, both because of the amount of work it is expected to perform and because of the traffic that is generated around it; and the system may be less reliable since the failure or inaccessibility of the central site would cause system unavailability.

Primary copy locking is a concurrency control algorithm that is useful in replicated databases where there may be multiple copies of a data item stored at different sites. One of the copies is designated as a primary copy, and it is this copy that has to be locked in order to access that item. The set of primary copies for each data item is known to all the sites in the distributed system, and the lock requests on behalf of transactions are directed to the appropriate primary copy. If the distributed database is not replicated, primary copy locking degenerates into a distributed locking algorithm.

In *distributed* (or *decentralized*) *locking*, the lock management duty is shared by all the sites in the system. The execution of a transaction involves the participation and coordination of lock managers at more than one site. Locks are obtained at each site where the transaction accesses a data item. Distributed locking algorithms do not have the overhead of centralized locking ones. However, both the communication overhead to obtain all the locks and the complexity of the algorithm are greater.

One side effect of all locking-based concurrency control algorithms is that they cause *deadlocks*. The detection and management of deadlocks in a distributed system is difficult. Nevertheless, the relative simplicity and better performance of locking algorithms make them more popular than alternatives such as *timestamp-based algorithms* or *optimistic concurrency control*. Timestamp-based algorithms execute the conflicting operations of transactions according to their timestamps, which are assigned when the transactions are accepted. Optimistic concurrency control algorithms work from the premise that conflicts among transactions are rare and proceed with executing the transactions up to their termination at which point a validation is performed. If the validation indicates that serializability would be compromised by the successful completion of that particular transaction, then it is aborted and restarted.

13.3.3 Reliability Protocols

We indicated earlier that distributed DBMSs are potentially more reliable because there are multiples of each system component, which eliminates single point of failure. This requires careful system design and the implementation of a number of protocols to deal with system failures.

In a distributed DBMS, four types of failures are possible: *transaction failures*, *site (system) failures*, *media (disk) failures*, and *communication line failures*. Transactions can fail for a number of reasons. Failure can be due to an error in the transaction caused by input data, as well as the detection of a present or potential deadlock. The usual approach that is followed in cases of transaction failure is to abort the transaction, resetting the database to its state prior to the start of the database.

Site (or system) failures are due to a hardware failure (e.g., processor, main memory, and power supply) or a software failure (bugs in system or application code). The effect of system failures is the loss of main memory contents. Therefore, any update to the parts of the database that are in the main memory buffers (also called *volatile database*) is lost as a result of system failures. However, the database that is stored in secondary storage (also called *stable database*) is safe and correct. To achieve this, DBMSs typically employ *logging protocols*, such as *Write-Ahead Logging* [9], which record changes to the database in system logs and move these log records and the volatile database pages to stable storage at appropriate times. From the perspective of distributed transaction execution, site failures are important since the failed sites cannot participate in the execution of any transaction.

Media failures refer to the failure of secondary storage devices that store the stable database. Typically, these failures are addressed by duplexing storage devices and maintaining archival copies of the database. Media failures are frequently treated as problems local to one site and therefore are not specifically addressed in the reliability mechanisms of distributed DBMSs.

The three types of failures described earlier are common to both centralized and distributed DBMSs. Communication failures, on the other hand, are unique to distributed systems. There are a number of types of communication failures. The most common ones are errors in the messages, improperly ordered messages, lost (or undelivered) messages, and line failures. Generally, the first two of these are considered to be the responsibility of the computer network protocols and are not addressed by the distributed DBMS. The last two, on the other hand, have an impact on the distributed DBMS protocols and, therefore, need to be considered in the design of these protocols. If one site is expecting a message from another site and this message never arrives, this may be because (a) the message is lost, (b) the line(s) connecting the two sites may be broken, or (c) the site which is supposed to send the message may have failed. Thus, it is not always possible to distinguish between site failures and communication failures. The waiting site simply timeouts and has to assume that the other site is unable to communicate. Distributed DBMS protocols have to deal with this uncertainty. One drastic result of line failures may be *network partitioning* in which the sites form groups where communication within each group is possible but communication across groups is not. This is difficult to deal with in the sense that it may not be possible to make the database available for access while at the same time guaranteeing its consistency.

Two properties of transactions are maintained by reliability protocols: *atomicity* and *durability*. Atomicity requires that either all the operations of a transaction are executed or none of them are (all-or-nothing). Thus, the set of operations contained in a transaction is treated as one atomic unit. Atomicity is maintained even in the face of failures. Durability requires that the effects of successfully completed (i.e., committed) transactions endure subsequent failures.

The enforcement of atomicity and durability requires the implementation of *atomic commitment protocols* and *distributed recovery protocols*. The most popular atomic commitment protocol is *two-phase commit* (2PC). The recoverability protocols are built on top of the local recovery protocols, which are dependent upon the supported mode of interaction (of the DBMS) with the operating system [10,11].

2PC is a very simple and elegant protocol that ensures the atomic commitment of distributed transactions. It extends the effects of local atomic commit actions to distributed transactions by insisting that all sites involved in the execution of a distributed transaction agree to commit the transaction before its effects are made permanent (i.e., all sites terminate the transaction in the same manner). If all the sites agree to commit a transaction, then all the actions of the distributed transaction take effect; if one of the

sites declines to commit the operations at that site, then all of the other sites are required to abort the transaction. Thus, the fundamental 2PC rule states

1. If even one site rejects to commit (which means it votes to abort) the transaction, the distributed transaction has to be aborted at each site where it executes.
2. If all the sites vote to commit the transaction, the distributed transaction is committed at each site where it executes.

The simple execution of the 2PC protocol is as follows. There is a *coordinator* process at the site where the distributed transaction originates and *participant* processes at all the other sites where the transaction executes. There are two rounds of message exchanges between the coordinator and the participants (hence the name 2PC protocol): in the first phase, the coordinator asks for votes regarding the transaction from the participants and determines the fate of the transaction according to the 2PC rule, and, in the second phase, it informs the participants about the decision. In the end, all of the participants and the coordinator reach the same decision. Two important variants of 2PC are the *presumed abort 2PC* and *presumed commit 2PC* [12]. These are important because they reduce the message and I/O overhead of the protocols. Presumed abort protocol is included in the X/Open XA standard and has been adopted as part of the International Standards Organization (ISO) standard for Open Distributed Processing.

One important characteristic of 2PC protocol is its *blocking* nature. Failures can occur during the commit process. As discussed earlier, the only way to detect these failures is by means of a time-out of the process waiting for a message. When this happens, the process (coordinator or participant) that timeouts follows a *termination protocol* to determine what to do with the transaction that was in the middle of the commit process. A non-blocking commit protocol is one whose termination protocol can determine what to do with a transaction in case of failures under any circumstance. In the case of 2PC, if a site failure occurs at the coordinator site and one participant site while the coordinator is collecting votes from the participants, the remaining participants cannot determine the fate of the transaction among themselves, and they have to remain blocked until the coordinator or the failed participant recovers. During this period, the locks that are held by the transaction cannot be released, which reduces the availability of the database.

13.3.4 Replication Protocols

In replicated distributed databases,* each logical data item has a number of physical instances. For example, the salary of an employee (*logical data item*) may be stored at three sites (*physical copies*). The issue in this type of a database system is to maintain some notion of consistency among the copies. The most discussed consistency criterion is *one copy equivalence*, which asserts that the values of all copies of a logical data item should be identical when the transaction that updates it terminates.

If replication transparency is maintained, transactions will issue read and write operations on a logical data item x. The replica control protocol is responsible for mapping operations on x to operations on physical copies of x ($x_1, \ldots, x_n$). A typical replica control protocol that enforces one copy serializability is known as *Read-Once/Write-All* (ROWA) protocol. ROWA maps each read on x [Read(x)] to a read on one of the physical copies x_i [Read(x_i)]. The copy that is read is insignificant from the perspective of the replica control protocol and may be determined by performance considerations. On the other hand, each write on logical data item x is mapped to a set of writes on *all* copies of x.

ROWA protocol is simple and straightforward, but it requires that all copies of all logical data items that are updated by a transaction be accessible for the transaction to terminate. Failure of one site may block a transaction, reducing database availability.

* Replication is not a significant concern in parallel DBMSs because the data are normally not replicated across multiple processors. Replication may occur as a result of data shipping during query optimization, but this is not managed by the replica control protocols.

A number of alternative algorithms have been proposed, which reduce the requirement that all copies of a logical data item be updated before the transaction can terminate. They relax ROWA by mapping each write to only a subset of the physical copies.

This idea of possibly updating only a subset of the copies, but nevertheless successfully terminating the transaction, has formed the basis of quorum-based voting for replica control protocols. The majority consensus algorithm can be viewed from a slightly different perspective: It assigns equal votes to each copy and a transaction that updates that logical data item can successfully complete as long as it has a majority of the votes. Based on this idea, an early *quorum-based voting algorithm* [13] assigns a (possibly unequal) vote to each copy of a replicated data item. Each operation then has to obtain a *read quorum* (V_r) or a *write quorum* (V_w) to read or write a data item, respectively. If a given data item has a total of V votes, the quorums have to obey the following rules:

1. $V_r + V_w > V$ (a data item is not read and written by two transactions concurrently, avoiding the read–write conflict)
2. $V_w > V/2$ (two write operations from two transactions cannot occur concurrently on the same data item, avoiding write–write conflict)

The difficulty with this approach is that transactions are required to obtain a quorum even to read data. This significantly and unnecessarily slows down read access to the database. An alternative quorum-based voting protocol that overcomes this serious performance drawback [14] has also been proposed. However, this protocol makes unrealistic assumptions about the underlying communication system. It requires that failures that change the network's topology are detected by all sites instantaneously, and that each site has a view of the network consisting of all the sites with which it can communicate. In general, communication networks cannot guarantee to meet these requirements. The single copy equivalence replica control protocols are generally considered to be restrictive in terms of the availability they provide. Voting-based protocols, on the other hand, are considered too complicated with high overheads. Therefore, these techniques are not used in current distributed DBMS products. More flexible replication schemes have been investigated where the type of consistency between copies is under user control. A number of *replication servers* have been developed or are being developed with this principle.

13.4 New Challenges and Emerging Solutions

The pervasiveness of the web has spurred all kinds of data-intensive applications and introduced significant challenges for distributed data management [15]. New data-intensive applications such as social networks, web data analytics, and scientific applications have requirements that are not met by the traditional distributed database systems in Figure 13.1. What has changed and made the problems much harder is the scale of the dimensions: very-large-scale distribution, very high heterogeneity, and high autonomy. In this section, we discuss some of these challenges and the emerging solutions to these challenges.

13.4.1 Cloud Data Management

Cloud computing is the latest trend in distributed computing and has been the subject of much debate. The vision encompasses on demand, reliable services provided over the Internet (typically represented as a cloud) with easy access to virtually infinite computing, storage, and networking resources. Through very simple web interfaces and at small incremental cost, users can outsource complex tasks, such as data storage, system administration, or application deployment, to very large data centers operated by cloud providers. Thus, the complexity of managing the software/hardware infrastructure gets shifted from the users' organization to the cloud provider. From a technical point of view, the grand challenge is to support in a cost-effective way the very large scale of the infrastructure, which has to manage lots of users and resources with high quality of service.

However, not all data-intensive applications are good candidates for being supported in a cloud [16]. To simplify, we can classify between the two main classes of data-intensive applications: Online Transaction Processing (OLTP) and Online Analytical Processing (OLAP). OLTP deals with operational databases of average sizes (up to a few terabytes), is write-intensive, and requires complete ACID transactional properties, strong data protection, and response time guarantees. OLAP, on the other hand, deals with historical databases of very large sizes (up to petabytes), is read-intensive, and thus can accept relaxed ACID properties. Furthermore, since OLAP data are typically extracted from operational OLTP databases, sensitive data can be simply hidden for analysis (e.g., using anonymization) so that data protection is not as crucial as in OLTP.

OLAP is more suitable than OLTP for cloud primarily because of two cloud characteristics [16]: elasticity and security. To support elasticity in a cost-effective way, the best solution that most cloud providers adopt is a shared-nothing cluster, which has a fully distributed architecture, where each node is made of processor, main memory, and disk and communicates with other nodes through message passing. Shared-nothing provides high scalability but requires careful data partitioning. Since OLAP databases are very large and mostly read-only, data partitioning and parallel query processing are effective [4]. However, it is much harder to support OLTP on shared-nothing systems because of ACID guarantees that require complex concurrency control. For these reasons and because OLTP databases are not very large, shared disk, where any processor has direct access to any disk unit through the interconnection network, is the preferred architecture for OLTP.

The second reason that OLTP is not so suitable for cloud is that highly sensitive data get stored at an untrusted host (the provider site). Storing corporate data at an untrusted third-party, even with a carefully negotiated Service Level Agreement with a reliable provider, creates resistance from some customers because of security issues. However, this resistance is much reduced for historical data, with anonymized sensitive data.

There is much more variety in cloud data than in scientific data since there are many different kinds of customers (individuals, small- and medium-size enterprises, large corporations, etc.). However, we can identify common features. Cloud data can be very large, unstructured (e.g., text-based) or semistructured, and typically append-only (with rare updates). Cloud users and application developers may be in high numbers, but not DBMS experts.

Generic data management solutions (e.g., relational DBMS) that have proven effective in many application domains (e.g., business transactions) are not efficient at dealing with emerging cloud applications, thereby forcing developers to build ad hoc solutions that are labor-intensive and that cannot scale. In particular, relational DBMSs have been lately criticized for their "one-size-fits-all" approach. Although they have been able to integrate support for all kinds of data (e.g., multimedia objects, XML documents, and new functions), this has resulted in a loss of performance and flexibility for applications with specific requirements because they provide both too much and too little. Therefore, it has been argued that more specialized DBMS engines are needed. For instance, column-oriented DBMSs, which store column data together rather than rows as in traditional row-oriented relational DBMSs, have been shown to perform more than an order of magnitude better on OLAP workloads. The "one-size-does-not-fit-all" counterargument generally applies to cloud data management as well.

Therefore, current data management solutions for the cloud have traded consistency for scalability, simplicity, and flexibility. As alternative to relational DBMS (which use the standard SQL language), these solutions have been recently quoted as "Not Only SQL" (NoSQL) by the database research community. Many of these solutions exploit large-scale parallelism, typically with shared-nothing clusters. Distributed data management for cloud applications emphasizes scalability, fault-tolerance, and availability, sometimes at the expense of consistency or ease of development. We illustrate this approach with three popular solutions: Bigtable, PNUTS, and MapReduce.

Bigtable is a database storage system initially proposed by Google for a shared-nothing cluster [17]. It uses the Google File System (GFS) [18] for storing structured data in distributed files, with fault-tolerance and availability. It also uses a form of dynamic data partitioning for scalability. There are also

open source implementations of Bigtable, such as Hadoop Hbase, as part of the Hadoop project of the Apache foundation (http://hadoop.apache.org), which runs on top of Hadoop Distributed File System, an open source implementation of GFS. Bigtable supports a simple data model that resembles the relational model, with multi-valued, timestamped attributes. It provides a basic application programming interface (API) for defining and manipulating tables, within a programming language such as C++, and various operators to write and update values and to iterate over subsets of data, produced by a scan operator. There are various ways to restrict the rows, columns, and timestamps produced by a scan, as in a relational select operator. However, there are no complex operators such as join or union, which need to be programmed using the scan operator. Transactional atomicity is supported for single row updates only. To store a table in GFS, Bigtable uses range partitioning on the row key. Each table is divided into partitions, called *tablets*, each corresponding to a row range.

PNUTS is a parallel and distributed database system for cloud applications at Yahoo! [19]. It is designed for serving web applications, which typically do not need complex queries, but require good response time, scalability, and high availability and can tolerate relaxed consistency guarantees for replicated data. PNUTS supports the relational data model, with arbitrary structures allowed within attributes of Blob type. Schemas are flexible as new attributes can be added at any time even though the table is being queried or updated, and records need not have values for all attributes. PNUTS provides a simple query language with selection and projection on a single relation. Updates and deletes must specify the primary key. PNUTS provides a replica consistency model that is between strong consistency and eventual consistency, with several API operations with different guarantees. Database tables are horizontally partitioned into tablets, through either range partitioning or hashing, which are distributed across many servers in a cluster (at a site).

Both Bigtable and PNUTS provide some variation of the relational model, a simple API or language for manipulating data, and relaxed consistency guarantees. They also rely on fragmentation (partitioning) and replication for fault-tolerance. Thus, they capitalize on the well-known principles of distributed data management.

MapReduce [20] is a good example of generic parallel data processing framework, on top of a distributed file system (GFS). It supports a simple data model (sets of (key, value) pairs), which allows user-defined functions (map and reduce). MapReduce was initially developed by Google as a proprietary product to process large amounts of unstructured or semistructured data, such as web documents and logs of web page requests, on large shared-nothing clusters of commodity nodes and produce various kinds of data such as inverted indices or uniform resource locators (URLs) access frequencies.

MapReduce enables programmers to express in a simple, functional style their computations on large data sets and hides the details of parallel data processing, load balancing, and fault-tolerance. The programming model includes only two operations, `map` and `reduce`, which we can find in many functional programming languages such as Lisp and ML. The Map operation is applied to each record in the input data set to compute one or more intermediate (key, value) pairs. The Reduce operation is applied to all the values that share the same unique key in order to compute a combined result. Since they work on independent inputs, map and reduce can be automatically processed in parallel, on different data partitions using many cluster nodes.

Different implementations of MapReduce are now available such as Amazon MapReduce (as a cloud service) or Hadoop MapReduce (as open source software). There is also much research going on improving the performance of the MapReduce framework, which performs full scans of data sets. For instance, Hadoop++ [21] introduces noninvasive, DBMS-independent indexing and join techniques to boost the performance of Hadoop MapReduce.

13.4.2 Scientific Data Management

Scientific data management has become a major challenge for the database and data management research community [22]. Modern science such as agronomy, bio-informatics, physics, and

environmental science must deal with overwhelming amounts of experimental data produced through empirical observation and simulation. Such data must be processed (cleaned, transformed, and analyzed) in all kinds of ways in order to draw new conclusions, prove scientific theories, and produce knowledge. However, constant progress in scientific observational instruments (e.g., satellites, sensors, and Large Hadron Collider) and simulation tools (that foster in silico experimentation, as opposed to traditional in situ or in vivo experimentation) creates a huge data overload. For example, climate modeling data are growing so fast that they will lead to collections of hundreds of exabytes expected by 2020.

Scientific data are also very complex, in particular, because of heterogeneous methods used for producing data, the uncertainty of captured data, the inherently multi-scale nature (spatial scale and temporal scale) of many sciences, and the growing use of imaging (e.g., satellite images), resulting in data with hundreds of attributes, dimensions, or descriptors. Processing and analyzing such massive sets of complex scientific data are, therefore, a major challenge since solutions must combine new data management techniques with large-scale parallelism in cluster, grid, or cloud environments [23].

Furthermore, modern science research is a highly collaborative process, involving scientists from different disciplines (e.g., biologists, soil scientists, and geologists working on an environmental project), in some cases from different organizations distributed in different countries. Since each discipline or organization tends to produce and manage its own data, in specific formats, with its own processes, integrating distributed data and processes gets difficult as the amounts of heterogeneous data grow.

Another major difficulty that is inherent with science is that knowledge and understanding may keep evolving, making it sometimes very hard to model data. Thus, we need to better understand the fundamental aspects of the scientific data management problem, in relationship with the main users, that is, scientists.

Despite their variety, we can identify common features of scientific data [24]: massive scale; manipulated through complex, distributed workflows; typically complex, for example, multidimensional or graph-based; with uncertainty in the data values, for example, to reflect data capture or observation; important metadata about experiments and their provenance; heavy floating-point computation; and mostly append-only (with rare updates). For reasons similar to those discussed for cloud data, relational DBMS are not efficient for dealing with most scientific data and NoSQL can be useful for scientific data.

The goal of scientific data management is to make scientific data easier to access, reproduce, and share by scientists of different disciplines and institutions. In recent international interdisciplinary workshops and conferences (e.g., http://www-conf.slac.stanford.edu/xldb), the following key requirements for scientific data management (that cannot be supported by current technology) have been identified [25]:

- Built-in support for managing and processing uncertain data (e.g., inaccurate data generated by faulty sensors or by imprecise observations) in distributed environments
- Rich representation of scientific data with an extensible data model that features multidimensional arrays, graph structures, sequences, etc.
- Distributed and parallel workflow execution involving large numbers of distributed processes and large amounts of heterogeneous data, with support of data provenance (lineage) to understand result data
- Scalability to hundreds of petabytes and thousands of nodes in high-performance computing environments (e.g., very large clusters), with high degrees of tolerance to failures
- Efficient data and metadata management, in particular, with semantics (ontologies), in order to help integrating data coming from different sources, with different formats and semantics
- Open source software in order to foster a community of contributors (from many different laboratories and institutes) and to insure data independence from proprietary systems

Addressing the aforementioned challenges and requirements is now on the agenda of a very active research community composed of scientists from different disciplines and data management researchers. For instance, the SciDB organization (http://www.scidb.org) is building an open source database system for scientific data analytics. SciDB supports an array data model, which generalizes the relational

model, with array operators. User-defined functions also allow for more specific data processing. SciDB will be certainly effective for similar applications for which the data is well understood (with well-defined models). However, to avoid that the one-size-fits-all argument applies to SciDB as well, the key question is: How generic should scientific data management be, without hampering application-specific optimizations? For instance, to perform scientific data analysis efficiently, scientists typically resort to dedicated indexes, compression techniques, and specific algorithms. Thus, generic techniques, inspired from the database (DB) research community should be able to cope with these specific techniques.

Genericity in data management encompasses two dimensions: data model, which provides data structures (captured by the data model), and data processing (inferred by the query language). Relational DBMS have initially provided genericity through the relational data model (that subsumes earlier data models) and a high-level query language (SQL). However, successive object extensions to include new data structures such as lists and arrays and support user-defined functions in a programming language have resulted in a yet generic, but more complex data model and language for the developers. Therefore, emerging NoSQL solutions tend to rely on a more specific data model (e.g., to deal with graphs, arrays, or sequences) with a simple set of operators easy to use from a programming language with a simple API.

In emerging solutions, it is interesting to witness the development of algebras to raise the level of abstraction for the programmer and provide automatic optimization. For example, Pig Latin [26] is an alternative data management solution to MapReduce with an algebraic query language. Another example is the approach proposed in [27] to deal with the efficient processing of scientific workflows that are computational and data-intensive, that is, manipulating huge amounts of data through specific programs and files and requiring execution in large-scale parallel computers. The authors propose an algebraic approach (inspired by relational algebra) and a parallel execution model that enable automatic optimization of scientific workflows. With the algebra, data are uniformly represented by relations and workflow activities are mapped to operators that have data-aware semantics. The execution model is based on the concept of activity activation, inspired from data activations proposed for parallel DBMS [28], which enables transparent distribution and parallelization of activities.

13.4.3 Stream Applications and Stream Data Management

The database systems that we have discussed until now consist of a set of unordered objects that are relatively static, with insertions, updates, and deletions occurring less frequently than queries. They are sometimes called *snapshot databases* since they show a snapshot of the values of data objects at a given point in time. Queries over these systems are executed when posed, and the answer reflects the current state of the database. In these systems, typically, the data are persistent and queries are transient.

However, the past few years have witnessed an emergence of applications that do not fit this data model and querying paradigm. These applications include network traffic analysis, financial tickers, online auctions, and applications that analyze transaction logs (such as web usage logs and telephone call records). In these applications, data are generated in real time, taking the form of an unbounded sequence (stream) of values. These are referred to as the *data stream* applications, and the systems that handle these types of data are known as *data stream management systems* (DSMS) (or stream data management systems) [29,30].

A data stream is commonly modeled as an append-only sequence of timestamped items that arrive in some order. Stream items may contain explicit source-assigned timestamps or implicit timestamps assigned by the DSMS upon arrival. In either case, the timestamp attribute may or may not be part of the stream schema, and therefore may or may not be visible to users. Stream items may arrive out of order (if explicit timestamps are used) and/or in preprocessed form. For instance, rather than propagating the header of each IP packet, one value (or several partially pre-aggregated values) may be produced to summarize the length of a connection between two IP addresses and the number of bytes transmitted.

A fundamental assumption of the data stream model is that new data are generated continually and in fixed order, although the arrival rates may vary across applications from millions of items per second (e.g., Internet traffic monitoring) down to several items per hour (e.g., temperature and humidity readings from a weather monitoring station). The ordering of streaming data may be implicit (by arrival time at the processing site) or explicit (by generation time, as indicated by a *timestamp* appended to each data item by the source). As a result of these assumptions, DSMSs face the following novel requirements:

1. Much of the computation performed by a DSMS is push-based or data-driven. Newly arrived stream items are continually (or periodically) pushed into the system for processing. On the other hand, a DBMS employs a mostly pull-based or query-driven computation model, where processing is initiated when a query is posed.
2. As a consequence of the preceding text, DSMS queries are *persistent* (also referred to as *continuous*, *long-running*, or *standing queries*) in that they are issued once, but remain active in the system for a possibly long period of time. This means that a stream of updated results must be produced as time goes on. In contrast, a DBMS deals with one-time queries (issued once and then "forgotten"), whose results are computed over the current state of the database.
3. The system conditions may not be stable during the *lifetime* of a persistent query. For example, the stream arrival rates may fluctuate and the query workload may change.
4. A data stream is assumed to have unbounded, or at least unknown, length. From the system's point of view, it is infeasible to store an entire stream in a DSMS. From the user's point of view, recently arrived data are likely to be more accurate or useful.
5. New data models, query semantics, and query languages are needed for DSMSs in order to reflect the facts that streams are ordered and queries are persistent.

The applications that generate streams of data also have similarities in the type of operations that they perform. We list a set of fundamental continuous query operations over streaming data as follows:

- *Selection*: All streaming applications require support for complex filtering.
- *Nested aggregation*: Complex aggregates, including nested aggregates (e.g., comparing a minimum with a running average) are needed to compute trends in the data.
- *Multiplexing and demultiplexing*: Physical streams may need to be decomposed into a series of logical streams, and conversely, logical streams may need to be fused into one physical stream (similar to group-by and union, respectively).
- *Frequent item queries*: These are also known as *top-k* or *threshold* queries, depending on the cut-off condition.
- *Stream mining*: Operations such as pattern matching, similarity searching, and forecasting are needed for on-line mining of streaming data.
- *Joins*: Support should be included for multi-stream joins and joins of streams with static metadata.
- *Windowed queries*: All of the aforementioned query types may be constrained to return results inside a window (e.g., the last 24 h or the last one hundred packets).

Proposed data stream systems resemble the abstract architecture shown in Figure 13.2. An input monitor regulates the input rates, perhaps by dropping items if the system is unable to keep up. Data are typically stored in three partitions: temporary working storage (e.g., for window queries that will be discussed shortly), summary storage for stream synopses, and static storage for metadata (e.g., physical location of each source). Long-running queries are registered in the query repository and placed into groups for shared processing, though one-time queries over the current state of the stream may also be posed. The query processor communicates with the input monitor and may re-optimize the query plans in response to changing input rates. Results are streamed to the users or temporarily buffered. Users may then refine their queries based on the latest results.

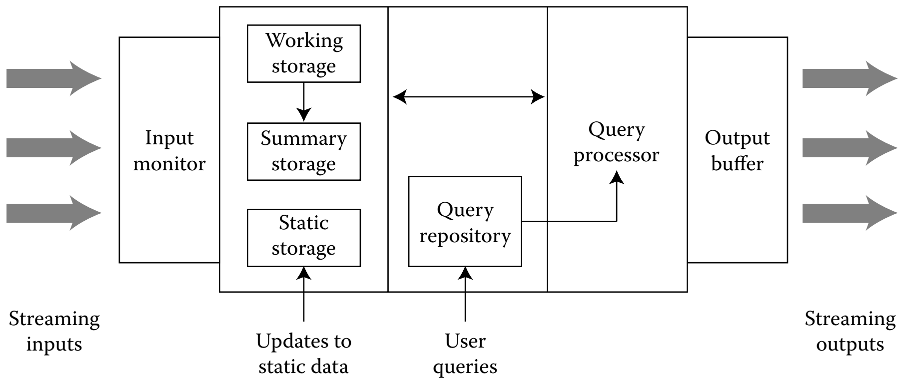

FIGURE 13.2 Abstract reference architecture for a DSMS. (Adapted from Özsu, T.M. and Valduriez, P., *Principles of Distributed Database Systems*, 3rd edn., Springer, 2011.)

Unbounded streams cannot be stored locally in a DSMS, and only a recent excerpt of a stream is usually of interest at any given time. In general, this may be accomplished using a *time-decay model*, and the most common way to achieve this is by means of *window models* where items within the window are given full consideration and items outside the window are ignored. There are a number of ways to classify windows, but the most common are the *logical*, or *time-based* windows, which are defined in terms of a time interval, and *physical*, or *count-based* windows, which are defined in terms of the number of tuples in the window.

Query languages developed for DSMSs fall into three classes: declarative, object-based, and procedural. Declarative languages have SQL-like syntax, but stream-specific semantics, as described earlier. Similarly, object-based languages resemble SQL in syntax, but employ DSMS-specific constructs and semantics, and may include support for streaming abstract data types and associated methods. Finally, procedural languages construct queries by defining data flow through various operators.

While the streaming languages discussed earlier may resemble standard SQL, their implementation, processing, and optimization present novel challenges. Some relational operators are blocking. For instance, prior to returning the next tuple, a nested loop join algorithm may potentially scan the entire inner relation and compare each tuple therein with the current outer tuple. Since data streams are unbounded, it is not possible to scan them, requiring nonblocking implementations. Some operators have non-blocking counterparts; in general, unblocking a query operator may be accomplished by re-implementing it in an incremental form, restricting it to operate over a window (more on this shortly), and exploiting stream constraints. However, there may be cases where an incremental version of an operator does not exist or is inefficient to evaluate, where even a sliding window is too large to fit in main memory, or where no suitable stream constraints are present. In these cases, compact stream summaries may be stored, and approximate queries may be posed over the summaries. This implies a trade-off between accuracy and the amount of memory used to store the summaries. An additional restriction is that the processing time per item should be kept small, especially if the inputs arrive at a fast rate.

Since windowed processing is crucial in DSMSs, we briefly discuss window operators. Sliding window operators process two types of events: arrivals of new tuples and expirations of old tuples. The actions taken upon arrival and expiration vary across operators. A new tuple may generate new results (e.g., join) or remove previously generated results (e.g., negation). Furthermore, an expired tuple may cause a removal of one or more tuples from the result (e.g., aggregation) or an addition of new tuples to the result (e.g., duplicate elimination and negation). Moreover, operators that must explicitly react to expired tuples (by producing new results or invalidating existing results) perform state purging eagerly (e.g., duplicate elimination, aggregation, and negation), whereas others may do so eagerly or lazily (e.g., join).

There is also the orthogonal problem of determining when tuples expire; sliding window operators must remove old tuples from their state buffers and possibly update their answers. Expiration from an individual time-based window is simple: A tuple expires if its timestamp falls out of the range of the window. That is, when a new tuple with timestamp *ts* arrives, it receives another timestamp, call it *exp*, that denotes its expiration time as *ts* plus the window length. In effect, every tuple in the window may be associated with a lifetime interval of length equal to the window size. Now, if this tuple joins with a tuple from another window, whose insertion and expiration timestamps are *ts′* and *exp′*, respectively, then the expiration timestamp of the result tuple is set to min (*exp*,*exp′*). That is, a composite result tuple expires if at least one of its constituent tuples expires from its windows. This means that various join results may have different lifetime lengths and furthermore, the lifetime of a join result may have a lifetime that is shorter than the window size. Moreover, as discussed earlier, the negation operator may force some result tuples to expire earlier than their *exp* timestamps by generating negative tuples. Finally, if a stream is not bounded by a sliding window, then the expiration time of each tuple is infinity.

In a count-based window, the number of tuples remains constant over time. Therefore, expiration can be implemented by overwriting the oldest tuple with a newly arrived tuple. However, if an operator stores state corresponding to the output of a count-based window join, then the number of tuples in the state may change, depending upon the join attribute values of new tuples. In this case, expirations must be signaled explicitly using negative tuples.

Window sizes can be set system-wide or by each application (or a combination of both). It is possible to use P2P techniques to dynamically increase the size of the sliding window [31].

In addition to the implementation of operators, there is the larger question of optimizing and processing queries, specifically continuous queries. A DSMS query optimizer performs tasks that are similar to a DBMS, but it must use an appropriate cost model and rewrite rules. Additionally, DSMS query optimization involves adaptivity, load shedding, and resource sharing among similar queries running in parallel, as summarized in the subsequent sections.

Traditional DBMSs use selectivity information and available indices to choose efficient query plans (e.g., those which require the fewest disk accesses). However, this cost metric does not apply to (possibly approximate) persistent queries, where processing cost per unit time is more appropriate. Alternatively, if the stream arrival rates and output rates of query operators are known, it may be possible to optimize for the highest output rate or to find a plan that takes the least time to output a given number of tuples. Finally, quality-of-service metrics such as response time may also be used in DSMS query optimization.

A DSMS query optimizer rewrites queries as usual, but with particular attention to the commutativity rules that arise in data stream systems. For example, selections and time-based sliding windows commute, but not selections and count-based windows. Furthermore, the notion of adaptivity is important in query rewriting; operators may need to be re-ordered on-the-fly in response to changes in system conditions. In particular, the cost of a query plan may change for three reasons: change in the processing time of an operator, change in the selectivity of a predicate, and change in the arrival rate of a stream. Initial efforts on adaptive query plans include mid-query re-optimization and query scrambling, where the objective is to preempt any operators that become blocked and schedule other operators instead. To further increase adaptivity, instead of maintaining a rigid tree-structured query plan, the Eddy approach [32] performs scheduling of each tuple separately by routing it through the operators that make up the query plan. In effect, the query plan is dynamically re-ordered to match current system conditions. This is accomplished by tuple routing policies that attempt to discover which operators are fast and selective, and those operators are scheduled first. A recent extension adds queue length as the third factor for tuple routing strategies in the presence of multiple distributed Eddies [33]. There is, however, an important trade-off between the resulting adaptivity and the overhead required to route each tuple separately. Adaptivity involves online reordering of a query plan and may therefore require that the internal state stored by some operators be migrated over to the new query plan consisting of a different arrangement of operators.

The stream arrival rates may be so high that not all tuples can be processed, regardless of the (static or run-time) optimization techniques used. In this case, two types of load shedding may be applied—random or semantic—with the latter making use of stream properties or quality-of-service parameters to drop tuples believed to be less significant than others. For an example of semantic load shedding, consider performing an approximate sliding window join with the objective of attaining the maximum result size. The idea is that tuples that are about to expire or tuples that are not expected to produce many join results should be dropped (in case of memory limitations), or inserted into the join state but ignored during the probing step (in case of CPU limitations). Note that other objectives are possible, such as obtaining a random sample of the join result.

In general, it is desirable to shed load in such a way as to minimize the drop in accuracy. This problem becomes more difficult when multiple queries with many operators are involved, as it must be decided where in the query plan the tuples should be dropped. Clearly, dropping tuples early in the plan is effective because all of the subsequent operators enjoy reduced load. However, this strategy may adversely affect the accuracy of many queries if parts of the plan are shared. On the other hand, load shedding later in the plan, after the shared sub-plans have been evaluated and the only remaining operators are specific to individual queries, may have little or no effect in reducing the overall system load.

One issue that arises in the context of load shedding and query plan generation is whether an optimal plan chosen without load shedding is still optimal if load shedding is used. It has been shown that this is indeed the case for sliding window aggregates, but not for queries involving sliding window joins.

Note that instead of dropping tuples during periods of high load, it is also possible to put them aside (e.g., spill to disk) and process them when the load has subsided. Finally, note that in the case of periodic re-execution of persistent queries, increasing the re-execution interval may be thought of as a form of load shedding.

13.4.4 Web Data Management

The World Wide Web ("WWW" or "web" for short) has become a major repository of data and documents. For all practical purposes, the web represents a very large, dynamic, and distributed data store, and there are the obvious distributed data management issues in accessing web data [34]. The web consists of "pages" that are connected by hyperlinks, and this structure can be modeled as a directed graph that reflects the hyperlink structure. In this graph, commonly referred to as the *web graph*, static HTML web pages are the nodes, and the links between them are represented as directed edges. Studying the web graph is obviously of interest to theoretical computer scientists, because it exhibits a number of interesting characteristics, but it is also important for studying data management issues since the graph structure is exploited in web search [35–37], categorization and classification of web content, and other web-related tasks. The important characteristics of the web graph are the following [38]:

- It is quite volatile. We already discussed the speed with which the graph is growing. In addition, a significant proportion of the web pages experience frequent updates.
- It is sparse. A graph is considered sparse if its average degree is less than the number of vertices. This means that the each node of the graph has a limited number of neighbors, even if the nodes are in general connected. The sparseness of the web graph implies an interesting graph structure that we discuss shortly.
- It is "self-organizing." The web contains a number of communities, each of which consists of a set of pages that focus on a particular topic. These communities get organized on their own without any "centralized control," and give rise to the particular subgraphs in the web graph.
- It is a "small-world network." This property is related to sparseness—each node in the graph may not have many neighbors (i.e., its degree may be small), but many nodes are connected through intermediaries. Small-world networks were first identified in social sciences where it was noted

that many people who are strangers to each other are connected by intermediaries. This holds true in web graphs as well in terms of the connectedness of the graph.

- It is a power law network. The in- and out-degree distributions of the web graph follow power law distributions. This means that the probability that a node has in- (out-) degree i is proportional to $1/i^{\alpha}$ for some $\alpha > 1$. The value of α is about 2.1 for in-degree and about 7.2 for out-degree.

The management of the very large, dynamic, and volatile web graph is an important issue. Two alternatives have been proposed for this purpose. The first is compressing the web graph, and the second is to develop special storage structures that allow efficient storage and querying (e.g., S-nodes [39]).

Web search is arguably the most common method for accessing the web. It involves finding "all" the web pages that are relevant (i.e., have content related) to keyword(s) that a user specifies. Naturally, it is not possible to find all the pages, or even to know if one has retrieved all the pages; thus the search is performed on a database of web pages that have been collected and indexed. Since there are usually multiple pages that are relevant to a query, these pages are presented to the user in ranked order of relevance as determined by the search engine.

A search engine consists of a number of components. One component is the *crawler*, which is a program used by a search engine to scan the web on its behalf and collect data about web pages. A crawler is given a starting set of pages—more accurately, it is given a set of URLs that identify these pages. The crawler retrieves and parses the page corresponding to that URL, extracts any URLs in it, and adds these URLs to a queue. In the next cycle, the crawler extracts a URL from the queue (based on some order) and retrieves the corresponding page. This process is repeated until the crawler stops. A control module is responsible for deciding which URLs should be visited next. The retrieved pages are stored in a page repository.

The *indexer module* is responsible for constructing indexes on the pages that have been downloaded by the crawler. While many different indexes can be built, the two most common ones are *text indexes* and *link indexes*. In order to construct a text index, the indexer module constructs a large "lookup table" that can provide all the URLs that point to the pages where a given word occurs. A link index describes the link structure of the web and provides information on the in-link and out-link state of pages.

The *ranking module* is responsible for sorting the large number of results so that those that are considered to be most relevant to the user's search are presented first. The problem of ranking has drawn increased interest in order to go beyond traditional information retrieval (IR) techniques to address the special characteristics of the web—web queries are usually small and they are executed over a vast amount of data.

There have also been attempts to perform declarative querying of web data and the efficient execution of these queries. Although these technologies are well developed for relational DBMSs, there are difficulties in carrying over traditional database querying concepts to web data. Perhaps the most important difficulty is that database querying assumes the existence of a strict schema. As noted earlier, it is hard to argue that there is a schema for web data similar to databases.* At best, the web data are *semistructured*—data may have some structure, but this may not be as rigid, regular, or complete as that of databases, so that different instances of the data may be similar but not identical (there may be missing or additional attributes or differences in structure). There are, obviously, inherent difficulties in querying schema-less data.

A second issue is that the web is more than the semistructured data (and documents). The links that exist between web data entities (e.g., pages) are important and need to be considered. Similar to search that we discussed in the previous section, links may need to be followed and exploited in executing web queries. This requires links to be treated as first-class objects.

A third major difficulty is that there is no commonly accepted language, similar to SQL, for querying web data. As we noted in the previous section, keyword search has a very simple language, but this is not

* We are focusing on the "open" web here; deep web data may have a schema, but it is usually not accessible to users.

sufficient for richer querying of web data. Some consensus on the basic constructs of such a language has emerged (e.g., path expressions), but there is no standard language. However, a standardized language for XML has emerged (XQuery), and as XML becomes more prevalent on the web, this language is likely to become dominant and more widely used.

One way to approach querying the web data is to treat it as a collection of semistructured data. Then, models and languages that have been developed for this purpose can be used to query the data. Semistructured data models and languages were not originally developed to deal with web data; rather they addressed the requirements of growing data collections that did not have as strict a schema as their relational counterparts. However, since these characteristics are also common to web data, later studies explored their applicability in this domain.

There have also been special purpose web query language developments. These directly address the characteristics of web data, particularly focusing on handling *links* properly. Their starting point is to overcome the shortcomings of keyword search by providing proper abstractions for capturing the content structure of documents (as in semistructured data approaches) as well as the external links. They combine the content-based queries (e.g., keyword expressions) and structure-based queries (e.g., path expressions).

13.4.5 P2P Data Management

In contrast to C/S DBMS, P2P systems [40] adopt a completely decentralized approach to distributed data sharing. By distributing data storage and processing across autonomous peers in the network, they can scale without the need for powerful servers. Popular examples of P2P systems such as BitTorrent and eMule have millions of users sharing petabytes of data over the Internet. Although very useful, these systems are quite simple (e.g., file sharing), support-limited functions (e.g., keyword search) and use simple techniques (e.g., resource location by flooding), which have performance problems. To deal with the dynamic behavior of peers that can join and leave the system at any time, they rely on the fact that popular data get massively duplicated. Furthermore, they are single-application systems and focus on performing one task, and it is not straightforward to extend them for other applications/functions [41].

To provide proper database functionality (schema, queries, replication, consistency, availability, etc.) over P2P infrastructures, the following data management issues must be addressed:

- Data location: Peers must be able to refer to and locate data stored in other peers.
- Data integration: When shared data sources in the system follow different schemas or representations, peers should still be able to access that data, ideally using the data representation used to model their own data.
- Query processing: Given a query, the system must be able to discover the peers that contribute relevant data and efficiently execute the query.
- Data consistency: If data are replicated or cached in the system, a key issue is to maintain the consistency between these duplicates.

Data location depends on the underlying infrastructure. P2P networks can be of two general types: pure and hybrid. *Pure P2P networks* are those where there is no differentiation between any of the network nodes—they are all equal. In *hybrid P2P networks*, on the other hand, some nodes are given special tasks to perform. Hybrid networks are commonly known as *super-peer systems*, since some of the peers are responsible for "controlling" a set of other peers in their domain. The pure P2P networks can be further divided into structured and unstructured networks. *Structured networks* tightly control the topology and message routing, for instance using a distributed hash table (DHT) or a tree structure, whereas in *unstructured networks*, each node can directly communicate with its neighbors and can join the network by attaching themselves to any node.

Structured P2P networks have emerged to address the scalability issues faced by unstructured P2P networks, which rely on flooding to locate data. They achieve this goal by tightly controlling the network

topology and the placement of resources. Thus, they achieve higher scalability at the expense of lower autonomy as each peer that joins the network allows its resources to be placed on the network based on the particular control method that is used.

Data integration raises issues that are more difficult than for designing database integration systems. Due to specific characteristics of P2P systems, for example, the dynamic and autonomous nature of peers, the approaches that rely on centralized global schemas no longer apply. The main problem is to support decentralized schema mapping so that a query on one peer's schema can be reformulated in a query on another peer's schema. The approaches, which are used by P2P data management systems for defining and creating the mappings between peers' schemas, can be classified as follows: pairwise schema mapping, common agreement mapping, and schema mapping using IR techniques. With pairwise schema mapping [42], each user defines the mapping between the local schema and the schema of any other peer that contains data that is of interest. Relying on the transitivity of the defined mappings, the system tries to extract mappings between schemas, which have no defined mapping. In common agreement mapping [43], the peers that have a common interest agree on a common schema description (CSD) for data sharing. Given a CSD, a peer schema can be specified using views. This is similar to the local-as-view approach in data integration systems, except that queries at a peer are expressed in terms of the local views, not the CSD. Another difference is that the CSD is not a global schema, that is, it is common to a limited set of peers with common interest. The last approach extracts the schema mappings at query execution time using IR techniques by exploring the schema descriptions provided by users. PeerDB [41] follows this approach for query processing in unstructured P2P networks.

P2P networks provide basic techniques for routing queries to relevant peers and this is sufficient for supporting simple, exact-match queries. For instance, a DHT provides a basic mechanism for efficient data lookup based on a key value. However, supporting more complex queries in P2P systems, particularly in DHTs, is difficult and has been the subject of much recent research. The main types of complex queries, which are useful in P2P systems, are top-k queries, join queries, and range queries.

With a top-k query, the user can specify a number *k* of the most relevant answers to be returned by the system. The degree of relevance (score) of the answers to the query is determined by a scoring function. An efficient algorithm for top-k query processing in centralized and distributed systems is the threshold algorithm (TA) [44]. TA assumes a general model based on lists of data items sorted by their local scores and is applicable for queries where the scoring function is monotonic, that is, any increase in the value of the input does not decrease the value of the output. The stopping mechanism of TA uses a threshold which is computed using the last local scores seen under sorted access in the lists. Many of the popular aggregation functions such as min, max, and average are monotonic. TA has been the basis for several TA-style algorithms in P2P systems. There are many database instances over which TA keeps scanning the lists although it has seen all top-k answers. Thus, it is possible to stop much sooner. Based on this observation, best position algorithms that execute top-k queries much more efficiently than TA have been proposed [45].

Structured P2P systems, in particular, DHTs are very efficient at supporting exact-match queries (i.e., queries of the form "*A* = *value*") but have difficulties with range queries. The main reason is that hashing tends to destroy the ordering of data which is useful to find ranges quickly. There are two main approaches for supporting range queries in structured P2P systems: extend a DHT with proximity or order-preserving properties [46], or maintain the key ordering with a tree-based structure [47].

The most efficient join algorithms in distributed and parallel databases are hash-based. Thus, the fact that a DHT relies on hashing to store and locate data can be naturally exploited to support join queries efficiently. A basic solution [48] is a variation of the traditional parallel hash join algorithm. The joined relations and the result relations have a namespace that indicates the nodes, which store horizontal fragments of the relation. Then it makes use of the DHT put method for distributing tuples onto a set of peers based on their join attribute so that tuples with same join attribute values are stored at the same peers. Then, joins can be performed locally at each peer, for example, using a hash join algorithm.

To increase data availability and access performance, P2P systems replicate data. However, different P2P systems provide very different levels of replica consistency. The earlier, simple P2P systems such as Gnutella and Kazaa deal only with static data (e.g., music files), and replication is "passive" as it occurs naturally as peers request and copy files from one another (basically, caching data). In more advanced P2P systems where replicas can be updated, there is a need for proper replica management techniques. Most of the work on replica consistency has been done only in the context of DHTs.

To improve data availability, most DHTs rely on data replication by storing data items at several peers by, for example, using several hash functions. If one peer is unavailable, its data can still be retrieved from the other peers that hold a replica. Some DHTs provide basic support for the application to deal with replica consistency, for example, Tapestry [49].

Although DHTs provide basic support for replication, the mutual consistency of the replicas after updates can be compromised as a result of peers leaving the network or concurrent updates. For some applications (e.g., agenda management), the ability to get the current data is very important. Supporting data currency in replicated DHTs requires the ability to return a current replica despite peers leaving the network or concurrent updates. The problem can be partially addressed by using data versioning, where each replica has a version number that is increased after each update. To return a current replica, all replicas need to be retrieved in order to select the latest version. However, because of concurrent updates, it may happen that two different replicas have the same version number, thus making it impossible to decide which one is the current replica. A more complete solution considers both data availability and data currency in DHTs, using distributed timestamping [50].

Replica reconciliation goes one step further than data currency by enforcing mutual consistency of replicas. Since a P2P network is typically very dynamic, with peers joining or leaving the network at will, eager replication solutions are not appropriate. The major solution is lazy distributed replication as used in OceanStore [51] and P-Grid [52]. APPA provides a general lazy distributed replication solution, which assures eventual consistency of replicas [53].

13.5 Summary

The impact of distributed and parallel data management technology on practice has been very high as all commercial DBMSs today have distributed and parallel versions. Parallel database systems are used to support very large databases (e.g., hundreds of terabytes or petabytes). Examples of applications that deal with very large databases are e-commerce, data warehousing, and data mining. Very large databases are typically accessed through high numbers of concurrent transactions (e.g., performing online orders on an electronic store) or complex queries (e.g., decision-support queries). The first kind of access is representative of OLTP applications while the second is representative of OLAP applications. Although both OLTP and OLAP can be supported by the same parallel database system (on the same multiprocessor), they are typically separated and supported by different systems to avoid any interference and ease database operation.

To address the requirements of new data-intensive applications (e.g., scientific applications or cloud), emerging solutions tend to rely on a more specific data model (e.g., Bigtable, which is a variant of the nested relational model) with a simple set of operators easy to use from a programming language. For instance, to address the requirements of social network applications, new solutions rely on a graph data model and graph-based operators. To address the requirements of scientific applications, SciDB [54] supports an array data model, which generalizes the relational model, with array operators. User-defined functions also allow for more specific data processing. In emerging solutions, it is interesting to witness the development of algebras, with specific operators, to raise the level of abstraction in a way that enables optimization, while making it easy to manipulate data from a programming language with a simple API.

Distributed and parallel database technology can now be used in two complementary large-scale distributed contexts: P2P and cloud. A P2P solution is appropriate to support the collaborative nature

of many applications, for example, scientific applications, as it provides scalability, dynamicity, autonomy, and decentralized control. Peers can be the participants or organizations involved in collaboration and may share data and applications while keeping full control over their (local) data sources. But for very-large-scale data analysis or to execute very large workflow activities, cloud computing is the right approach as it can provide virtually infinite computing, storage, and networking resources.

14.1 Introduction

With rapidly growing collections of images, news programs, music videos, movies, digital television programs, and training and education videos on the Internet and corporate intranets, new tools are needed to harness digital media for different applications, ranging from image and video cataloging, to media archival and search, multimedia authoring and synthesis, and smart browsing. In recent years, we have witnessed the growing momentum in building systems that can query and search video collections efficiently and accurately for desired video segments, just in the manner text search engines on the web have enabled easy retrieval of documents containing a required piece of text located on a server anywhere in the world. Digital video archival and management systems are also important to postproduction houses, broadcast studios, stock footage houses, and advertising agencies working with large videotape and multimedia collections, to enable integration of content in their end-to-end business processes. Further, since the digital form of videos enables rapid content editing, manipulation, and synthesis, there is burgeoning interest in building cheap, personal desktop video production tools.

An image and video content management system must allow archival, processing, editing, manipulation, browsing, and search and retrieval of image and video data for content repurposing, new program production, and other multimedia interactive services. Annotating or describing images and videos manually through a preview of the material is extremely time consuming, expensive, and unscalable. A content management system, for example, in a digital television studio serves different sets of users, including the program producer who needs to locate material from the studio archive, the writer who

needs to write a story about the airing segment, the editor who needs to edit in the desired clip, the librarian who adds and manages new material in the archive, and the logger who annotates the material in terms of its metadata such as medium ID, production details, and other pertinent information about the content that allows it to be located easily. Therefore, a content management tool must be scalable and highly available, ensure integrity of content, and enable easy and quick retrieval of archived material for content reuse and distribution. Automatic extraction of image and video content descriptions is highly desirable to ease the pain of manual annotation and to provide a consistent language of content description when annotating large video collections.

In order to answer user queries during media search, it is crucial to define a suitable representation for the media, their metadata, and the operations to be applied to them. The aim of a data model is to introduce an abstraction between the physical level (data files and indices) and the conceptual representation, together with some operations to manipulate the data. The conceptual representation corresponds to the conceptual level of the American National Standards Institute (ANSI) relational database architecture [106], where algebraic optimization and algorithm selections are performed. Optimization at the physical level (data files and indices) consists of defining indices and selecting the right access methods to be used in query processing.

This chapter surveys techniques used to extract descriptions of multimedia data (mainly image and video) through automated analysis and current database solutions in managing, indexing, and querying of multimedia data. The chapter is divided into two parts: multimedia data analysis and database techniques for multimedia. The multimedia data analysis part comprises Section 14.2, which presents common features used in image databases and the techniques to extract them automatically, and Section 14.3, which discusses audio and video content analysis, extraction of audiovisual descriptors, as well as the fusion of multiple media modalities. The second part comprises Section 14.4, which presents an example of database models defined for multimedia data, and Section 14.5, which discusses similarity search in multimedia. Finally, Section 14.6 concludes the chapter.

14.2 Image Content Analysis

Existing work in image content analysis could be coarsely categorized into two groups based on the features employed. The first group indexes an image based on low-level features such as color, texture, and shape, while the second group attempts to understand the semantic content of images by using mid- to high-level features, as well as by applying more complex analysis models. This section surveys representative work in both groups.

14.2.1 Low-Level Image Content Analysis

Research is this area proposes to index images based on low-level features, which are easy to extract and fast to implement. Some well-known content-based image retrieval (CBIR) systems such as query by image content (QBIC) [39], multimedia analysis and retrieval system (MARS) [54], WebSEEK [119], and Photobook [102] have employed these features for image indexing, browsing, and retrieval, with reasonable performance achieved. However, due to the low-level nature of these features, there still exists a gap between the information revealed by these features and the real image semantics. Obviously, more high-level features are needed to truly understand the image content. In the following, we review some commonly used image features, including color, texture, and shape.

14.2.1.1 Color

Color is one of the most recognizable elements of image content. It is widely used as a feature for image retrieval due to its invariance to image scaling, translation, and rotation. Key issues in color feature extraction include the selection of color space and the choice of color quantization scheme.

A color space is a multidimensional space in which different dimensions represent different color components. Theoretically, any color can be represented by a linear combination of the three primary

colors, red (R), green (G), and blue (B). However, the RGB color space is not perceptually uniform, and equal distances in different areas and along different dimensions of this space do not correspond to equal perception of color dissimilarity. Therefore, other color spaces, such as CIELAB and CIEL*u*v*, have been proposed. Other widely used color spaces include YCbCr, YIQ, YUV, HSV, and Munsell spaces. Readers are referred to [20] for more detailed descriptions on color spaces. The MPEG-7 standard [85], formally known as the "multimedia content description interface," has adopted the RGB, YCbCr, and HSV color spaces, as well as linear transformation matrices with reference to RGB.

Quantization is used to reduce the color resolution of an image. Since a 24 bit color space contains 2^{24} distinct colors, using a quantized map can considerably decrease the computational complexity of color feature extraction. The most commonly used color quantization schemes are uniform quantization, vector quantization, tree-structured vector quantization, and product quantization. MPEG-7 supports linear and nonlinear quantization, as well as quantization via lookup tables.

Three widely used color features for images (also called color descriptors in MPEG-7) are global color histogram, local color histogram, and dominant color. The global color histogram captures the color content of the entire image while ignoring information on spatial layout. Specifically, a global color histogram represents an image I by an N-dimensional vector $H(I) = [H(I, j), j = 1, 2, \ldots, N]$, where N is the total number of quantized colors and $H(I, j)$ is the number of pixels having color j.

In contrast, the local color histogram representation considers the position and size of each individual image region so as to describe the spatial structure of the image color. For instance, Stricker and Dimai [123] segmented each image into five nonoverlapping spatial regions, from which color features were extracted and subsequently used for image matching. In [96], a scalable blob histogram was proposed, where the term blob denotes a group of pixels with a homogeneous color. This descriptor is able to distinguish images, containing objects of different sizes and shapes, without performing color segmentation.

The dominant color representation is considered to be one of the major color descriptors due to its simplicity and its association with human perception. Various algorithms have been proposed to extract this feature. For example, Ohm and Makai took the means of color clusters (the cluster centroids) as dominant colors of images [97]. Considering that human eyes are more sensitive to changes in smooth regions than changes in detailed ones, Deng et al. proposed the extraction of dominant colors by hierarchically merging similar and unimportant color clusters while leaving distinct and more important clusters untouched [34].

Other commonly used color feature representations include color correlogram [52] and color moments [123]. Specifically, the color correlogram captures the local spatial correlation of pairs of colors and is a second-order statistic on the color distribution. It is rotation, scale, and (to some extent) viewpoint invariant. Moreover, it is designed to tolerate moderate changes in appearance and shape due to viewpoint changes, camera zoom, noise, and compression. Therefore, color correlogram representations have been widely used in video copy detection [92] and video concept modeling and detection [140]. On the other hand, color moments are mainly adopted to overcome undesirable color quantization effects and are defined as the moments of the distribution formed by RGB triplets in a given image. Note that by using a proper combination of moments it is possible to normalize against photometric changes. Such combinations are called color moment invariants. Color moments and color moment invariants have been applied to applications such as CBIR.

14.2.1.2 Texture

Texture refers to visual patterns with properties of homogeneity that do not result from the presence of only a single color or intensity. Tree bark, clouds, water, bricks, and fabrics are some examples of textures. Typical texture features include contrast, uniformity, coarseness, roughness, frequency, density, and directionality, which contain important information about the structural arrangement of surfaces as well as their relationship to the surrounding environment. So far, much research effort has been devoted to texture analysis due to its usefulness and effectiveness in applications such as pattern recognition, computer vision, and image retrieval.

There are two basic types of texture descriptors: statistical and transform based. The statistical approach explores the gray-level spatial dependence of textures and extracts meaningful statistics as the texture representation. For example, Haralick et al. [47] proposed the representation of textures using co-occurrence matrices that capture gray-level spatial dependence. They also performed a statistical analysis of the spatial relationships of lines, as well as the properties of their surroundings. Interestingly, Tamura et al. addressed this topic from a totally different viewpoint [125]: based on psychological measurements, they claimed that the six basic textural features should be coarseness, contrast, directionality, line-likeness, regularity, and roughness. Two well-known CBIR systems, QBIC and MARS, have adopted this representation. Other texture representations may involve a subset of the aforementioned six features, such as contrast, coarseness, and directionality.

Two other commonly used statistical texture features are edge histograms [85] and histograms of oriented gradient (HOG) [29]. Edge histograms describe the distribution of edges in terms of both frequency and directionality of the brightness gradients within an image. HOG extends the edge orientation histogram or histogram of gradient directions by means of computation over a dense grid of uniformly spaced cells. Furthermore, improved performance is often achieved within overlapping local contrast normalization. Edge histograms and HOG features have been widely applied in image and video object detection and recognition [45].

In recent years, local binary pattern (LBP) feature has gradually gained in popularity, especially in computer vision applications. Specifically, the LBP operator is defined as a grayscale invariant texture measure, derived from a general definition of texture in a local neighborhood. Its properties of invariance under monotonic gray-level changes, together with its computational simplicity, have made it a very good feature for applications such as facial expression recognition [151].

Commonly used transforms for texture extraction include the discrete cosine transform (DCT), the Fourier–Mellin transform, the polar Fourier transform, the Gabor transform, and the wavelet transform. Alata et al. [5] proposed the classification of rotated and scaled textures using a combination of the Fourier–Mellin transform and a parametric 2D spectrum estimation method (Harmonic Mean Horizontal Vertical). In [130], Wan and Kuo reported their work on texture feature extraction for Joint Photographic Experts Group (JPEG) images based on the analysis of DCT–AC coefficients. Chang and Kuo [23] presented a tree-structured wavelet transform, which provided a natural and effective way to describe textures that have dominant middle- to high-frequency subbands. Readers are referred to [20] for a detailed description on texture feature extraction.

Building upon Gabor features, Oliva and Torralba proposed the GIST feature for the characterization of scenes [98]. GIST features concatenate spatially pooled Gabor filter responses in different scales and orientations in different spatial blocks of the image. They have been successfully applied to directly represent, understand, and recognize image scenes, bypassing the segmentation and processing of individual objects or regions. Natseve et al. have also successfully applied GIST (along with other features) for video copy detection and video event detection in their text retrieval conference—video retrieval evaluation (TRECVID) 2010 effort [92].

14.2.1.3 Shape

Compared to color and texture, the representation of shape is inherently much more complex. Two major steps are required to extract a shape feature: object segmentation and shape representation.

Although object segmentation has been studied for decades, it remains a very difficult research topic in computer vision. Existing image segmentation techniques include the global threshold-based approach, the region growing approach, the split and merge approach, the edge-detection-based approach, the color- and texture-based approach, and the model-based approach. Generally speaking, it is difficult to achieve perfect segmentation due to the complexity of individual object shapes, as well as the existence of shadows and noise.

Existing shape representation approaches can be categorized into the following three classes: boundary-based representation, region-based representation, and their combination. Boundary-based

representations emphasize the closed curve that surrounds the shape. Numerous models have been proposed to describe this curve, including chain codes [42], polygons [28], circular arcs [38], splines [33], explicit and implicit polynomials [61], boundary Fourier descriptors, and Universidade Nova de Lisboa (UNL) descriptors [16]. Region-based representations, on the other hand, emphasize the area within the closed boundary. Various descriptors have been proposed to model interior regions, such as moment invariants [77], Zernike moments [62], morphological descriptor [81], and pseudo-Zernike moments. Generally speaking, region-based moments are invariant to image's affine transformations. Readers are referred to [147] for more details.

Recent work in shape representation includes the finite element method (FEM), the turning function, and the wavelet descriptor. Besides the earlier work in 2D shape representation, research effort has been devoted to 3D shape representation. Readers are referred to [20] for more detailed discussions on shape features.

14.2.2 Key Points and Bag of Visual Words

14.2.2.1 Key Point Extraction

Key points (or points of interest) are used to describe local features of images. The most popular technique is the scale invariant feature transform (SIFT) proposed by Lowe in 2004 [82]. SIFT is designed to be scale, rotation, and shift invariant so that it can be reliably applied to object recognition and image matching. The four basic steps in extracting SIFT features include scale-space extrema detection, key point localization, orientation assignment, and key point descriptor formation.

Based upon SIFT, several other variants have been subsequently proposed, including the speeded up robust features (SURFs) [10], the principal component analysis-based representation of SIFT features (PCA-SIFT) [60], and the rotation-invariant feature transform (RIFT) [66]. SURF is a high-performance scale- and rotation-invariant interest point detector/descriptor, which has been claimed to approximate or even outperform SIFT with respect to repeatability, distinctiveness, and robustness. PCA-SIFT differs from SIFT in terms of calculation of the image gradients and the definition of gradient regions. It also applies PCA to further reduce the feature dimension. Finally, RIFT is a rotation-invariant generalization of SIFT, constructed using circular normalized patches, which are divided into concentric rings of equal width. A gradient orientation histogram is then computed within each ring.

Key point extraction methods such SIFT represent an image as a large collection of feature vectors, each of which describes a specific key point in the image. Visual words are obtained by grouping similar key points into clusters. Hence, a visual word represents a specific visual pattern and the set of visual words represent a visual word vocabulary. An image can then be represented as a collection (or "bag") of visual words. The entire process from the key point extraction to the final visual word vectors is illustrated by Figure 14.1.

14.2.3 Mid- to High-Level Image Content Analysis

Research in this area attempts to index images based on semantics content in the form of salient image objects. To achieve this goal, various mid- to high-level image features, as well as more complex analysis models, have been proposed. An example reported in [34] uses a low-dimensional color indexing scheme based on homogeneous image regions. After first applying a color segmentation method (JSEG) to obtain homogeneous regions, the colors within each region are quantized and grouped into a small number of clusters. Finally, color centroids together with their relative weights were used as feature descriptors.

Some approaches attempt to understand image content by learning its semantic concepts. For example, Minka and Picard [88] developed a system that first generated segmentations or groups of image

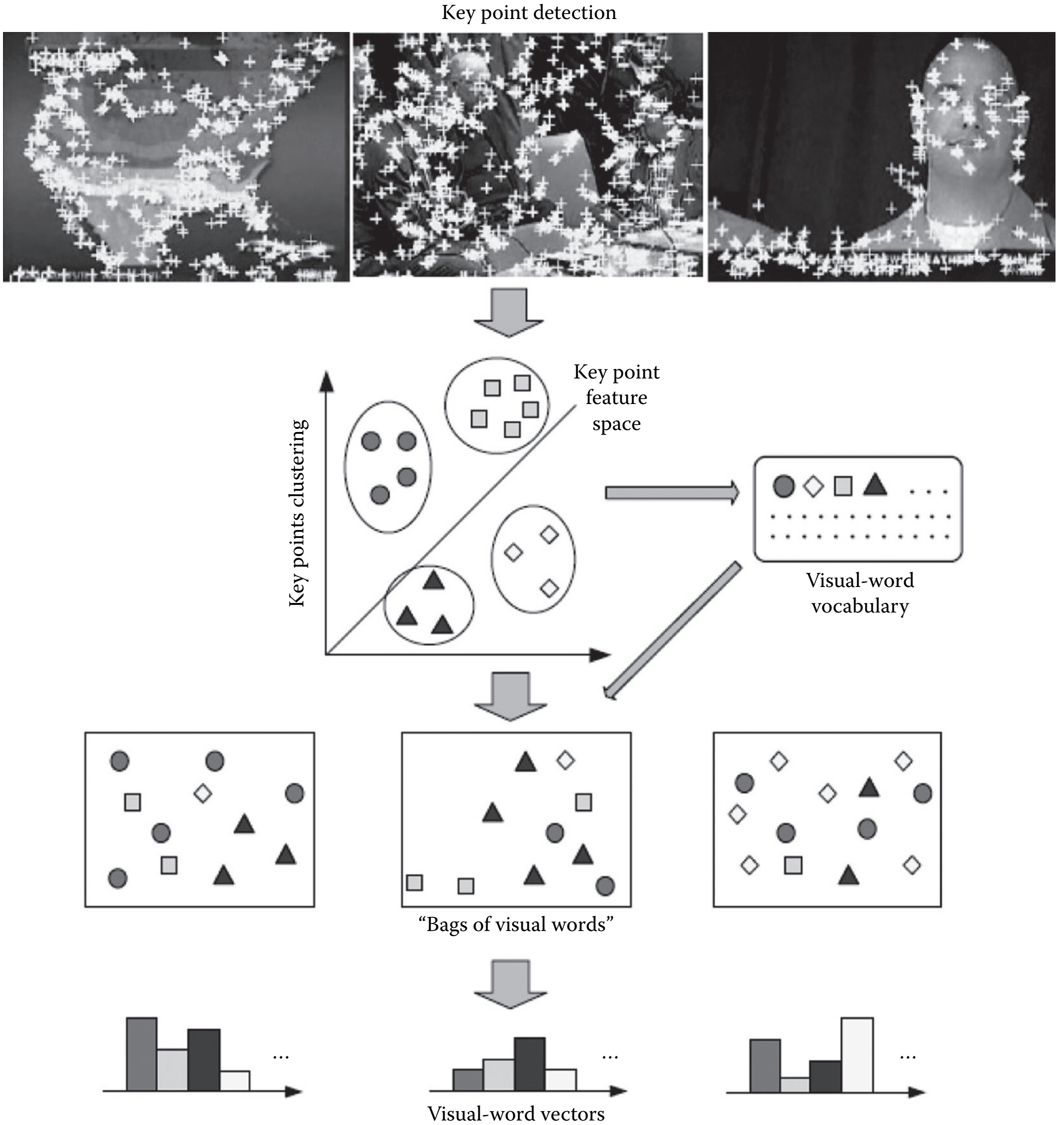

FIGURE 14.1 From key points to bag of words. (From Yang, L. et al., *Multimedia Inform. Retrieval* (*MIR*), 1, 265, September 2007.)

regions using various feature combinations. The system was later improved by learning from the user input to decide which combinations best represent predetermined semantic categories. The system, however, requires supervised training over various parts of the image. In contrast, Li et al. proposed the detection of detect salient image regions based on segmented color and orientation maps without any human intervention [74].

Targeting the construction of a moderately large lexicon of semantic concepts, Naphade et al. proposed a support vector machine (SVM) learning system for detecting 34 visual concepts, including 15 scene concepts (e.g., outdoors, indoors, landscape, cityscape, sky, beach, mountain, and land) and 19 object concepts (e.g., face, people, road, building, tree, animal, text overlay, and train) [91]. Using the TREC 2002 benchmark corpus for training and validation, this system has achieved reasonable performance with moderately large training samples.

With the proliferation of photo sharing services and general purpose sites with photo sharing capabilities, such as Flickr and Facebook, automated image annotation and tagging have become a problem of great interest [35,107,115,129]. In fact, image annotation has been extensively studied by several research communities, including the image retrieval, computer vision community, multimedia and web, and human–computer interface communities. Several benchmark evaluation campaigns such as Pattern Analysis, Statistical Modelling and Computational Learning (PASCAL) and TRECVID have been launched to encourage and evaluate algorithms and systems developed along this line [56,117,128]. In [50], Houle et al. proposed a knowledge propagation algorithm as a neighborhood-based approach to effectively propagate knowledge associated to a few objects of interest to an entire image database. In [114,121], an ontology is utilized for image annotation. The keywords are organized in a hierarchical structure to help remove semantic ambiguities. Photo sharing services such as Facebook and Flickr contain community-contributed media collections, and applying social knowledge can help rerank, filter, or expand image tags. Both [43] and [115] were Flickr image tag recommendation systems developed based on tag concurrence and intertag aggregation. Liu et al. further incorporated image similarity into tag co-occurrence and evaluated the system with subjective labeling of tag usefulness [79]. In [135], an end-to-end image tagging system was presented along with a detailed user evaluation of the accuracy and value of the machine-generated image tags. Several important issues in building an image tagging system were addressed, including the design of tagging vocabulary, taxonomy-based tag refinement, classifier score calibration for effective tag ranking, and selection of valuable tags as opposed to accurate ones.

Finally, there is a recent trend to adopt a new computing paradigm, known as data-intensive scalable computing (DISC), to keep up with the increasingly high-volume multimedia modeling and analysis. DISC proposes the use of a data parallel approach to processing Big Data, which are large volumes of data in the order of terabytes or petabytes [19]. DISC has defined a new research direction, and with the emergence of Big Data, research effort has been devoted to large-scale data processing. For example, in [140], Yan et al. proposed an algorithm called robust subspace bagging (RB-SBag) for large-scale semantic concept modeling, along with its MapReduce implementation (MapReduce [30–32] was proposed by Google as a leading example of DISC). RB-SBag combines both random subspace bagging and forward model selection into a unified approach. Evaluations conducted on more than 250K images and several standard TRECVID benchmark data sets have showed that the RB-SBag approach can achieve a more than ten-fold speedup over baseline SVM-based approaches.

14.3 Video Content Analysis

Video content analysis, which consists of visual content analysis, audio content analysis, as well as multimodality analysis, has attracted an enormous interest in both academic and corporate research communities. This research appeal, in turn, encourages areas that are primarily built upon content analysis modules such as video abstraction, video browsing, and video retrieval to be actively developed. In this section, a comprehensive survey of these research topics will be presented.

14.3.1 Visual Content Analysis

The first step in video content analysis is to extract its content structure, which could be represented by a hierarchical tree exemplified in Figure 14.2 [72]. As shown, given a continuous video bitstream, we first segment it into a series of cascaded video shots, where a shot contains a set of contiguously recorded image frames. Because the content within a shot is always continuous, in most cases, one or more frames (known as key frames) can be extracted to represent its underlying content. However, while the shot forms the building block of a video sequence, this low-level structure does not directly correspond to the video semantics. Moreover, this processing often leads to a far too fine segmentation of the video data. That risks the obscuration of its semantic meaning.

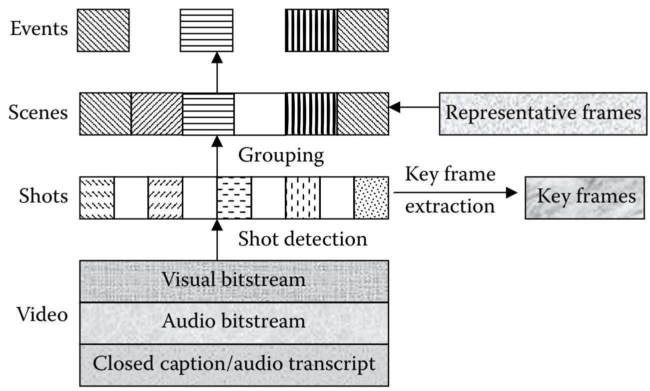

FIGURE 14.2 A hierarchical representation of video content.

Most recent work attempts to understand the video semantics through the extraction of the underlying video scenes, where a scene is defined as a collection of semantically related and temporally adjacent shots that depicts and conveys a high-level concept or story. A common approach to video scene extraction is to group semantically related shots into a scene.

Nevertheless, not every scene can be associated with a meaningful theme. For example, in feature films, there are certain scenes that are used only to establish story environment without involving any thematic topics. Therefore, it is necessary to find important scenes that contain specific thematic topics, such as dialogue or sports highlight. In the area of surveillance video analysis, users are likely to be interested only in video segments that contain specific or abnormal patterns or behaviors. In this chapter, such video units or segments are referred to as events.

Finally, it is also important to automatically annotate videos or detect specific video concepts, so as to better understand video content and facilitate video browsing, search, and navigation at a semantic level. This section reviews previous work on the detection of video shots, scenes, and events, as well as video annotation.

14.3.1.1 Video Shot Detection

A shot can be detected by identifying the camera transitions, which may be either abrupt or gradual. Abrupt transition, also called a camera break or cut, occurs when the content changes significantly between two consecutive frames. In contrast, a gradual transition is usually associated with special effects such as a dissolve, wipe, fade-in, and fade-out, where a smooth change in content is observed over a consecutive sequence of frames.

Existing work in shot detection can be generally categorized into the following five classes: pixel based, histogram based, feature based, statistics based, and transform based. The pixel-based approach detects the shot change by counting the number of pixels, which have changed from one frame to the next. However, while this approach may be the simplest way to detect the content change between two frames, a pixel-based method may be too sensitive to object and camera motion. Consequently, the histogram-based approach, which detects content change by comparing the histograms of neighboring frames, has gained more popularity as histograms are invariant to image rotation, scaling, and transition. In fact, it has been reported that histogram methods can achieve good trade-offs between the accuracy and speed [78].

The feature-based approach applies features such as intensity edge [146] and visual rhythm [26] to identify the shot boundary. Other technologies such as image segmentation and object tracking have also been employed. On the other hand, information such as mean and standard deviation of pixel intensities are exploited by statistics-based approach. Finally, transform-based methods use hidden Markov model (HMM) or Markov random field (MRF) to model shot transitions.

The topic of shot detection has matured in recent years, as the current research literature contains approaches that can perform reasonably well on real-world applications [145].

14.3.1.2 Video Scene and Event Detection

Existing scene detection approaches can be classified into two: model based and model-free. With the former category, specific structure models are constructed for up specific video applications by exploiting scene characteristics, discernible logos, or marks. For example, in [148], temporal and spatial structures were defined for the parsing of TV news, where the temporal structure was modeled by a series of shots, including anchorperson shots, news shots, commercial break shots, and weather forecast shots. Meanwhile, the spatial structure was modeled by four frame templates, with each containing either two anchorpersons, one anchorperson, one anchorperson with an upper-right news icon, or one anchorperson with an upper-left news icon. Some other work in this direction has tried to integrate multiple media cues such as visual, audio, and text (closed captions or audio transcripts) to extract scenes from real TV programs.

Compared to the model-based approach, which has very limited applications, the model-free approach can be applied to very generic situations. Work in this area can be categorized into three classes according to the use of visual, audio, or audiovisual cues. In visual-based approaches, color or motion information is utilized to locate the scene boundary. For example, Yeung et al. proposed to detect scenes by grouping visually similar and temporally close shots [142]. Moreover, they also constructed a transition graph to represent the detected scene structure. Compressed video sequences were used in their experiments. Other work in this area has involved the cophenetic dissimilarity criterion or a set of heuristic rules to determine the scene boundary.

Pure audio-based work was reported in [150], where the original video was segmented into a sequence of audio scenes such as speech, silence, music, speech with music, song, and environmental sound based on low-level audio features. In [89], sound tracks in films and their indexical semiotic usage were studied based on an audio classification system that could detect complex sound scenes as well as the constituent sound events in cinema. Specifically, it has studied the car chase and the violence scenes for action movies based on the detection of their characteristic sound events such as horns, sirens, car crashes, tires skidding, glass breaking, explosions, and gunshots.

However, due to the difficulty of precisely locating the scene boundaries based on audio cues alone, more recent research has concentrated on the integration of multiple media modalities for more robust results [37,53,120]. For example, three types of media cues including audio, visual, and motion were employed by [53] to extract semantic video scenes from broadcast news. They considered two types of scenes, N-type (normal scenes) characterized by a long-term consistency of chromatic composition, lighting conditions, and sound and M-type (montage scenes) characterized by visual features for such attributes as lighting conditions, location, and time of creation. N-type scenes were further classified into pure dialogue scenes (with a simple repetitive visual structure among the shots), progressive scenes (linear progression of visuals without repetitive structure), and hybrid scenes (dialogue embedded in a progressive scene) [124]. An integration of audio and visual cues was reported in [73], where audio cues including ambient noise, background music, and speech were cooperatively evaluated with visual feature extraction in order to precisely locate the scene boundary. Special movie editing patterns were also considered in this work.

Compared to that of a scene, the concept of an event is more subjectively defined as it can take on different meanings for different applications many assign. For example, an event could be the highlight of a sports video or an interesting topic in a video document. In [84], a query-driven approach was presented for the detection of topics of discussion by using image and text contents of query foil presentation. While multiple media sources were integrated in their framework, identification results were mainly evaluated in the domain of classroom presentations due to the special features adopted. In contrast, work on sports highlight extraction mainly focuses on detecting the announcer's speech, the audience ambient speech noise, the game-specific sounds (e.g., the sounds of batting in baseball), and various other background

noises (e.g., the cheering of audiences). Targeting the analysis of movie content, Li et al. proposed the detection of three types of events, namely, 2-speaker dialogues, multispeaker dialogues, and hybrid events, by exploiting multiple media cues and special movie production rules [75,95].

In the computer vision community, event detection usually refers to abnormal event detection or abnormal object activity detection/recognition in surveillance videos. For example, in [8], Basharat et al. first built the trajectories of objects by tracking them using an appearance model and then, based on the measurement of the abnormality of each trajectory, detecting anomalous behaviors such as unusual path taken by pedestrians or moving object with abnormal speed and size. Similar ideas were also proposed in [104], where a nonparametric object trajectory representation was employed to detect abnormal events. In [63], a space–time MRF model was proposed to detect abnormal activities in videos. The nodes in the MRF graph corresponded to a grid of local regions in the video frames, and neighboring nodes in both space and time were associated with links. Experimental results on several surveillance videos showed that the MRF model could not only localize atomic abnormal activities in a busy video scene but also capture global-level abnormalities caused by irregular interactions between local activities. Also aiming at modeling both spatial and temporal activities, Xiang and Gong developed an HMM to incrementally and adaptively detect abnormal object behaviors [134].

In contrast with the detection of moving objects, Tian et al. proposed a framework for the robust efficient detection of abandoned and removed objects in complex surveillance videos based on background subtraction and foreground analysis complemented by tracking [127]. Three Gaussian mixture models (GMMs) were applied to model the background, as well as to detect static foreground regions. Context information of the foreground masks was also exploited to help determine the type of static regions. Finally, a person-detection process was integrated to distinguish static objects from stationary people. The proposed method has been tested on a large set of real-world surveillance videos and has demonstrated its robustness to quick changes in lighting and occlusions in complex environments.

A very comprehensive and scalable object and event detection, indexing, and retrieval system, the IBM Smart Surveillance Solution, was presented in [41]. The system allows user to define criteria for alerts with reference to a specific camera view. The criteria can be parked car detection, trip wire, etc. Moreover, it automatically generates descriptions for the events that occur in the scene and stores them in an indexed database to allow users to perform rapid search. Analytics supported by this system include moving object (such as people and vehicle) detection and tracking, object classification with calibration, object behavior analysis, color classification, and license plate recognition. The system has been successfully deployed in several large cities such as Chicago and New York City for public safety monitoring in urban environments.

In recent years, with the proliferation of videos on social media sites such as YouTube, detecting real-world events from user-uploaded videos and monitoring and tracking their usage and life cycle have attracted increasing interests from researchers in both multimedia analysis and social media mining communities. Cha et al. conducted a large-scale YouTube measurement study to characterize content category distributions, as well as to track exact duplicates of popular videos [22]. In [136], Xie et al. developed a large-scale event monitoring system for YouTube videos based on proposed visual memes. A meme is a short video segment frequently remixed and reposted by different authors. Once memes were extracted from tens of thousands of YouTube videos, the authors built a graph model to model the interactions among them, with people and content as nodes and meme postings as links. Then using this model they were able to derive graph metrics that capture content influence and user roles. The authors observed that over half of the event videos on YouTube contained remixed content, that about 70% of video creators participated in video remixing, and that over 50% of memes were discovered and reposted within 3 h after their first appearance.

14.3.1.3 Video Annotation

The automatic annotation of videos at the semantic concept level has recently emerged as a very active topic within the multimedia research community. Video annotation entails a multilabeling process whereby a video clip is associated with one or more labels. For example, a video clip can be tagged

as "garden," "plant," "flower," and "lake" simultaneously. The concepts of interest in this case usually include a wide range of categories describing scenes, objects, events, and certain named entities.

Current research on video annotation follows three general paradigms: individual-concept detection, context-based concept fusion (CBCF), and integrated multilabeling [105]. Research involving the first paradigm generally uses binary classification to detect each individual concept, thus treating a collection of concepts as isolated points. A typical approach in this case is to build a binary detector for each concept and create either a presence or absence label based on video content modeling and analysis. An alternative is to stack a set of binary detectors into a single discriminative classifier [113]. The left branch in Figure 14.3 illustrates a typical process flow.

Solutions proposed according to the individual-concept detection paradigm have only achieved limited success, as they do not model the inherent correlations between real-world concepts. For example, the presence of "sky" often occurs together with the presence of "cloud," whereas "ocean" normally does not co-occur with "truck." Furthermore, while simple concepts can be directly modeled from low-level features, it could be rather difficult to learn individual models for such complex concepts as "political protest." Instead, complex concepts could be inferred from other more primitive concepts based on correlation. For example, if the concepts of "people," "walking," and "banners" are detected, then they likely indicate the presence of the concept "political protest."

In contrast, studies of context-based concept fusion add a second step after individual-concept detection by fusing multiple concepts together. A CBCF-based active learning approach was proposed in [123] where user annotations were solicited for a small number of concepts from which the remainder of the concept could be inferred. In [132], Wu et al. proposed an ontology-based multiclassification learning method or video concept detection. Each concept was first independently modeled by a classifier, and then a predefined ontology hierarchy was applied to improve the detection accuracy of individual classifiers. An alternative fusion strategy was proposed in [49], where logistic regression (LR) was applied to fuse individual detections. In [118], Smith et al. described a two-step discriminative model fusion (DMF) approach to derive unknown or indirect relationship among concepts by constructing model vectors based on detection scores of individual classifiers. An SVM was then trained to refine the detection results of these classifiers. The typical flow of this process is illustrated by the center branch in Figure 14.3.

While it is intuitive to exploit the contextual relationship among concepts to improve their detection accuracy, CBCF approaches do not always provide stable performance improvement. The reasons are twofold. First, detection errors in individual classifiers can be propagated to the fusion step, thereby degrading the overall performance. Second, the training data for the conceptual fusion may be insufficient, leading to overfitting. Models learned in this way usually lack generalization capability.

Recently, Qi et al. proposed a third paradigm that simultaneously classifies concepts and models their correlations using a so-called correlative multilabel (CML) framework [105]. This approach, illustrated by the right-most branch (Figure 14.3), follows the principle of least commitment [86] in the sense that both learning and optimization are performed in a single step, thus avoiding the error propagation problem of CBCF. Moreover, since the entire training data are simultaneously used for modeling both individual concepts and their correlations, the risk of overfitting is significantly reduced. Experiments conducted on the benchmark TRECVID 2005 data sets have demonstrated its superior performance over other state-of-the-art approaches.

Xie et al. proposed probabilistic visual concept trees for modeling large visual semantic taxonomies and demonstrated their effective use in visual concept detection in a limited setup [137]. They considered three salient attributes for a real-world visual taxonomy: concept semantics, image appearance, and data statistics. They proposed a multifaceted concept forest structure within which these attributes are expressed in the form of parent–child relationships, mutually exclusive relationships, and multiple aspect labelings. They then used the proposed visual concept tree model to encode the multifaceted concept forest under uncertainty. The probabilistic visual concept trees were designed to extend the functionalities of several predecessors, such as the Bayes Net and tree-structured taxonomy [138].

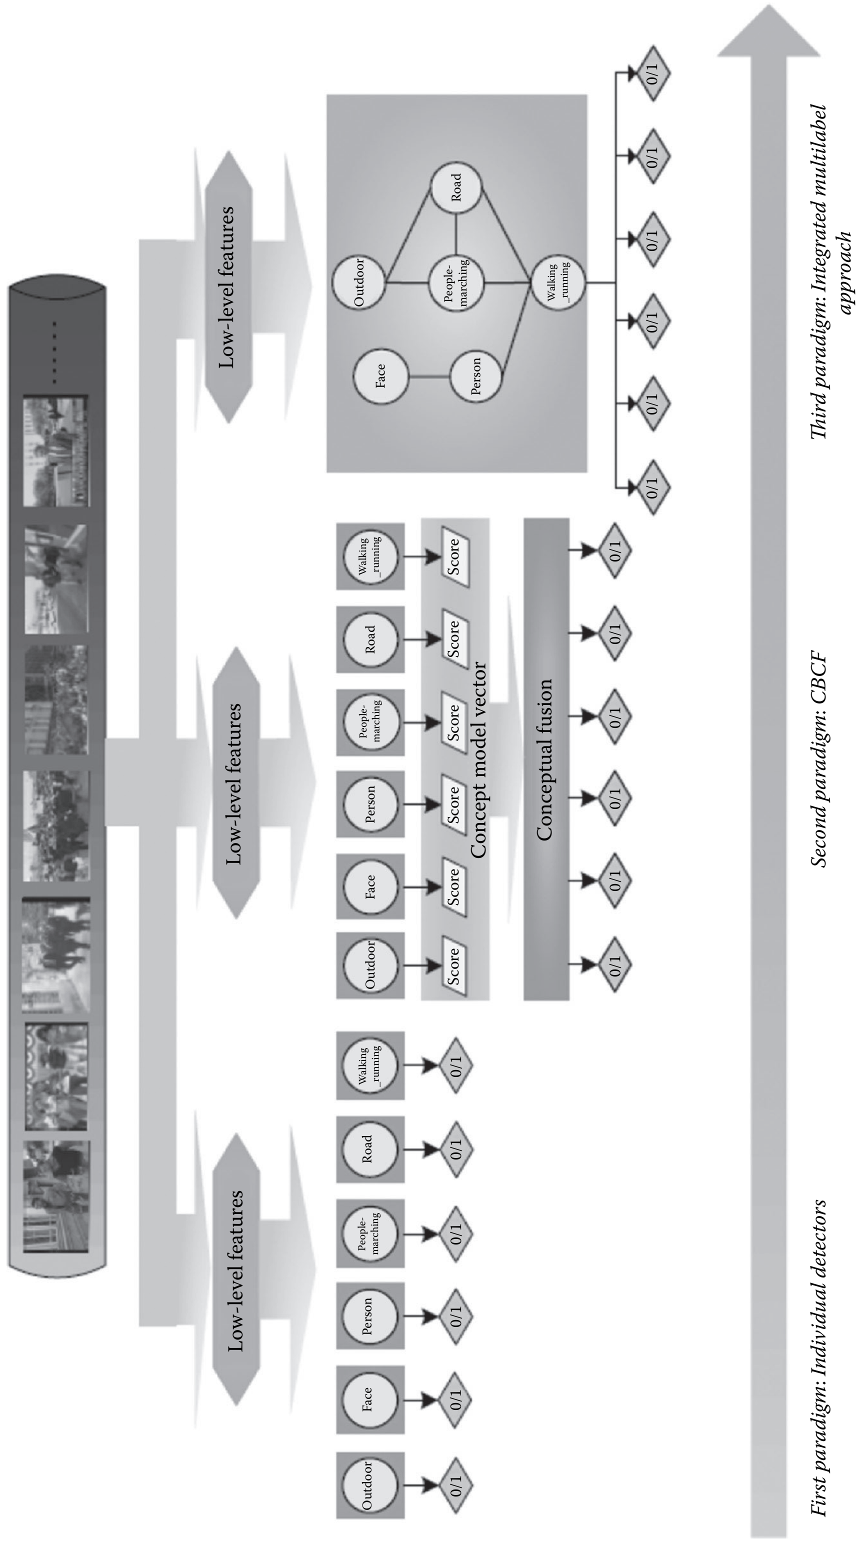

FIGURE 14.3 Flowcharts for three different paradigms of typical multilabel video annotation methods. (From Qi, G. et al., *ACM Multimedia*, 1, 17, 2007.)

They are also capable of supporting inference with the junction tree algorithm. Evaluations conducted over 60K web images with a taxonomy of 222 concepts have shown that probabilistic visual concept trees are capable of effective representation of visual semantic taxonomies, including the encoding of hierarchy, mutually exclusion, and multifaceted concept relationships under uncertainty.

14.3.2 Audio Content Analysis

Existing research on content-based audio data analysis is still quite limited and can be categorized into the following two classes.

14.3.2.1 Audio Segmentation and Classification

One basic problem in audio segmentation is the discrimination between speech and music, which are the two most important audio types. In general, a relatively high accuracy can be achieved when distinguishing speech from music, since their respective signals are significantly different in their spectral distributions as well as their temporal change patterns. A general solution is to first extract various audio features such as the average zero-crossing rate (ZCR) and the short-time energy from the signals, then distinguish the two sound types based on the feature values. For example, 13 audio features calculated in time, frequency, and cepstrum domains were employed in [112] for the purpose of classification. The authors also examined and compared several popular classification schemes, including the multidimensional Gaussian maximum a posteriori estimator, the GMM, a spatial partitioning scheme based on *k*-*d*-trees, and a nearest neighbor classifier.

State-of-the-art classification algorithms are usually based more on sound. For example, Wyse and Smoliar classified audio signals into three types, including "music," "speech," and "others" [133]. Music was first detected based on the average length of the interval during which peaks were within a narrow frequency band; speech was then separated out by tracking the pitches. Research in [103] was devoted to analyze the signal's amplitude, frequency, and pitch. Simulations were also conducted on human audio perception, the results of which were utilized to segment the audio data and to recognize the music component. More recently, Zhang and Kuo presented an extensive feature extraction and classification system for audio content segmentation and classification purposes [149]. Five audio features including energy, average ZCR, fundamental frequency, and spectral peak tracks were extracted to fulfill the task. A two-step audio classification scheme was proposed in [83], where in the first step, speech and nonspeech were discriminated using *k*-nearest neighbor (*K*-NN) and line spectral pair vector quantization (LSPVQ) classification schemes. In the second step, the nonspeech signals were further classified into music, environment sounds, and silence using a feature thresholding scheme. In [70], an SVM-based audio classification mechanism was proposed to assist the content analysis of instructional videos such as presentations and lectures.

In [143], Yu et al. proposed the combination of local summarization and multilevel locality-sensitive hashing (LSH) for multivariant audio retrieval. Based on spectral similarity, they divide each audio track into multiple continuously correlated periods of variable length. This removes a significant part of the redundant information but provides support for more compact but yet accurate descriptions. They then compute weighted mean chroma features for each of these periods. Then, by exploiting the characteristics of the content description, they adapted a two-level LSH scheme for efficiently delineating a narrow relevant search region. In [144], Yu et al. proposed MultiProbe histograms as global summaries of audio feature sequences that retain local temporal acoustic correlations by concatenating major bins of adjacent chroma features. They then exploited the order statistics of the MultiProbe histograms to more efficiently organize and probe LSH tables. The resulting approximate retrieval method is faster than exact *K*-NN retrieval while still achieving useful accurate rates.

14.3.2.2 Audio Analysis for Video Indexing

Five different video classes, including news report, weather report, basketball, football, and advertisement, were distinguished in [80] using both multilayer neural networks (MNNs) and HMMs.

Features such as the silence ratio, the speech ratio, and the subband energy ratio were extracted to fulfill this task. It was shown that while MNN worked well in distinguishing among reports, games, and advertisements, it had difficulty in classifying different types of reports or games. On the contrary, the use of HMM increased the overall accuracy, but it could not achieve good classification of the five video types. In [101], features such as the pitch, the short-time average energy, the band energy ratio, and the pause rate were first extracted from the coded subband of an MPEG audio clip; these features were then integrated to characterize the clip as either silence, music, or dialogue. Another approach to video indexing based on music and speech detection was proposed in [87], where image processing techniques were applied to the spectrogram of the audio signals. The spectral peaks of music were recognized by applying an edge-detection operator and the speech harmonics were detected with a comb filter.

Li et al. [69] proposed to the detection of discussion scenes in instructional videos by identifying scenes that contain narrations and dialogues using on an audio classification scheme.

14.3.3 Fusion of Multiple Modalities

Recently, researchers have begun to focus their attention on the analysis of video content by integrating multiple modalities including audio, visual, and textual cues. Multiple media sources usually complement each other to convey the complete semantics of the content. Consequently, by taking all sources into account, we can achieve better understanding of the content.

A general solution for the fusion of multiple modalities is to first perform individual visual, audio, or textual content analysis to obtain separate sets of analysis results and then to combine them based on fusion rules, perhaps under a probabilistic framework. Another popular way of media integration is to employ different information sources at different processing stages. For example, we can first employ visual cues to generate coarse-level results, then introduce audio cues to refine the results. However, when and how to efficiently and effectively integrate multiple media sources still remain an open issue in need of further study.

In [36,71], a system called metadata automated generation for instructional content (MAGIC) was presented, which aimed to assist content authors and course developers in generating metadata for learning materials and information assets, so as to enable wider reuse of these objects across departments and organizations. The MAGIC metadata generation environment consisted of a set of text and video processing tools to recover the underlying narrative structures of learning materials, including text analysis components for extracting titles and keywords, a taxonomy and classification system for automatically assigning documents to specific taxonomy, and audio and video segmentation and analysis components for segmenting learning videos. Various video analysis algorithms and machine-learning techniques have been applied to both visual features extracted from the video track and aural features computed from the audio track. The segments were further annotated with text features extracted from time-stamped closed caption text based on advanced text analysis. Experiments conducted on a midsized set of videos from various Department of Homeland Security agencies have demonstrated the advantage of integrating multiple modalities in video content analysis to assist more intuitive and effective video browsing, search, and authoring.

An atomic topical segment detection framework was proposed in [76] for instructional videos to facilitate topic-based video navigation and offer efficient video authoring. A comprehensive text analysis component was first developed to extract informative text cues such as keyword synonym sets and sentence boundary information from video transcripts. These text cues were then integrated with various audiovisual cues, such as silence/music breaks and speech similarity, to identify topical segments. Encouraging user feedback has been gathered regarding the usefulness of such system.

Aiming at the detection of affective content in movies, Xu et al. exploited cues from multiple modalities to represent emotions and emotional atmosphere [139]. They first generated midlevel representations from low-level features by integrating audio sounds, dialogue, and subtitles with the visual analysis and then applied them to infer the affective content. Experiments carried out on different movie genres have validated the effectiveness of their approach.

A comprehensive study and large-scale tests of web video categorization methods were reported in [141]. Considering that web videos are characterized by a much higher diversity of quality, subject, style, and genres compared with traditional video programs, the authors concluded that multiple modalities should be employed. In addition to the application of low-level visual and audio features, they proposed two new modalities: a semantic modality and a surrounding text modality. The semantic modality was represented by three types of features: concept histogram, visual word vector model, and visual word latent semantic analysis (LSA). Meanwhile, the text modality was represented by titles, descriptions, and tags of web videos. A comprehensive experiment on evaluating the effectiveness of proposed feature representations with three different classifiers, including SVM, GMM, and manifold ranking, was conducted over 11K web videos, and a mean average precision of 0.56 has been achieved.

An earlier work on classifying news videos using multimodal information was reported in [24]. The authors first applied Fisher's linear discriminant (FLD) to select a smaller number of discriminative features from a large set of features extracted from image, audio, transcript, and speech; they then concatenated the projections into a single synthesized feature vector to represent the scene content. Using SVM as the classifier, they have achieved good performance on anchor and commercial detection in the TREC 2003 video track benchmark. A later development of this work was described in [48], wherein a hybrid approach to improving semantics extraction from news video was proposed. Through extensive experiments, the authors demonstrated the value of careful parameter tuning, exploitation of multiple feature sets and multilingual linguistic resources, applying text retrieval approaches for image features, as well as establishing synergies between multiple concepts through undirected graphical models.

A novel visual feature-based machine-learning framework called IBM multimedia analysis and retrieval system (IMARS) was presented in [6,93], which aimed to make digital photos and videos searchable through large-scale semantic modeling and classification. IMARS consists of two important components. First, the multimedia analysis engine applies machine-learning techniques to model semantic concepts in images and videos from automatically extracted visual descriptors. It then automatically assigns labels to unseen content to improve its searching, filtering, and categorization capabilities. Second, the multimedia search engine combines content-based, model-based, semantic concept-based, and speech-based text retrieval for more effective image and video searching.

14.3.4 Video Abstraction

Video abstraction, as the name implies, generates a short summary of a long video. A video abstract is a sequence of still or moving images, which represent the video essence in a very concise way. Video abstraction is primarily used for video browsing and is an indispensable part of any video indexing and retrieval system.

There are two fundamentally different kinds of video abstracts: still- and moving-image abstracts. The still-image abstract, also known as a static storyboard or video summary, is a small collection of key frames extracted or generated from the underlying video source. The moving-image abstract, also known as a moving storyboard or video skim, consists of a collection of image sequences, as well as the corresponding audio abstract extracted from the original sequence. It is itself a video clip but of considerably shorter length than the original.

There are basically two types of video skim: the summary sequence and the highlight. A summary sequence is used to provide users an impression about the entire video content, while a highlight generally only contains a relatively small number of interesting video segments. A good example of a video highlight is the movie trailer, which only shows a few very attractive scenes without revealing the story's ending.

Compared to video skimming, video summarization has attracted much more research interest. Based on the way the key frames are extracted, existing work in this area can be categorized into the following three classes: sampling based, shot based, and segment based.

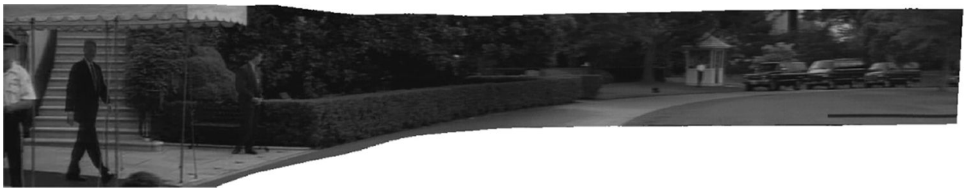

FIGURE 14.4 A mosaic image generated from a panning sequence.

Most of the earlier work on summarization work was sampling based, where key frames were either randomly chosen or uniformly sampled from the original video. Sampling is the simplest way to extract key frames, yet it often fails to adequately represent the video content. More sophisticated methods thus tend to extract key frames by adapting to the dynamic video content using shots. Because a shot is taken within a continuous capture period, a natural and straightforward approach is to extract one or more key frames from each shot. Features such as color and motion have been applied to find the optimal key frames in this case. Mosaics have also been proposed for the representation of shots. One such example is shown in Figure 14.4 [85].

A major drawback of using one or more key frames for each shot is that it does not scale well for long video sequences. Therefore, researchers have proposed to work with an even higher-level video units or segments. A video segment could be a scene, an event, or even the entire sequence.

14.4 Modeling and Querying Multimedia Data

Most research prototypes and applications in multimedia directly organize and search for the vectors obtained from content analysis (see Section 14.5). However, a few database models for multimedia have been proposed in the 1990s and early 2000s. A database model defines the theoretical foundation by which the data are stored and retrieved. The models were proposed as extensions of existing database models (relational, object-oriented, and semistructured models).

14.4.1 Multimedia Database Model as an Extension of Object-Relational Models

Defining a multimedia data model as an extension of the relational or object-relational model is appealing, as the database world is dominated by the relational database model. In [110], an image is stored in a table T (h: *Integer*, x_1: X_1, …, x_n: X_n), where h is the image identifier and x_i is an image feature attribute of domain (or type) X_i (note that classical attributes can be added to this minimal schema). The tuple corresponding the image k is indicated by $T[k]$. Each tuple is assigned a real-valued score (ζ) such that $T[k]$. ζ is a distance between the image k and the current query image. The value of ζ is assigned by a scoring operator $\Sigma_T(s)$ given a scoring function s: $\Sigma_T(s)[k] \cdot \zeta = s(T[k] \cdot x_1, \ldots, T[k] \cdot x_n)$.

Since many image queries are based on distance measures, a set of distance functions (d: $X \times X \rightarrow [0,1]$) is defined for each feature type X. Given an element x: X and a distance function d defined on X, the scoring function s assigns $d(x)$, a distance from x to every element of X. In addition, a set of score combination operators $\Diamond : [0,1] \times [0,1] \rightarrow [0,1]$ is defined. New selection and join operators defined on the image table augmented with the scores allow the selection of the n images with lowest scores, the images whose scores are less than a given score value ρ and the images from a table $T = T(h$: *Integer*, x_1:X_1, …, x_n: $X_n)$ that match images from a table $Q = Q(h$: *Integer*, y_1: Y_1, …, y_n: $Y_n)$, based on score combination functions as follows:

- K-NNs: $\sigma_k^{\#}(\Sigma_T(s))$ returns the k rows of the table T with the lowest distance from the query.
- Range query operator: $\sigma_\rho < (\Sigma_T(s))$ returns all the rows of the table T with a distance less than ρ.
- $\Diamond$ *Join*: $T \bowtie Q$ joins the tables T and Q on their identifiers h and returns the table $W = W(h$: *Integer*, x_1: X_1,…,x_n: X_n,y_1: Y_1,…,y_n: $Y_n)$. The distance in the table W is defined as $W \cdot d = T \cdot d \Diamond Q \cdot d$.

In [111], the same authors proposed a design model with four kinds of feature dependencies that can be exploited for the design of efficient search algorithms. For multimedia data models defined as the object-relational model, an extension of SQL called SQL/MM was proposed as a standard query language [122].

14.4.2 Multimedia Database Model as Extension of Object-Oriented Models

Multimedia content description is application dependent. The vectors and related similarity functions are defined for specific applications. Because they allow the user to provide methods for specific classes, object-oriented models have been extended to support multimedia data [68,99]. The distributed image database management system (DISIMA) model [99] is an example of a multimedia data model defined as an extension of an object-oriented data model. In the DISIMA model, an image is composed of physical salient objects (regions of the image) whose semantics are given by logical salient objects representing real-world objects. Both images and physical salient objects can have visual properties. The DISIMA model uses an object-oriented concept and introduces three new types: image, physical salient objects, and logical salient objects as well as operators to manipulate them.

Images and related data are manipulated through predicates and operators defined on images; physical and logical salient objects are used to query the images. They can be directly used in calculus-based queries to define formulas or in the definition of algebraic operators. Since the classical predicates $\{=, <, \leq, >, \geq\}$ are not sufficient for images, a new set of predicates were defined for use on images and salient objects:

- Contain predicate: Let i be an image and o be an object with a behavior *pso* that returns the set of physical salient objects associated with o: $contains(i,o) \Leftrightarrow \exists p \in o \cdot pso \wedge p \in i \cdot pso$.
- Shape similarity predicates: Given a shape similarity metric d_{shape} and a similarity threshold ε_{shape}, two shapes s and t are similar with respect to d_{shape} if $d_{shape}(s,t) \leq \varepsilon_{shape}$. In other words, $shape\_similar(s,t,\varepsilon_{shape}) \Leftrightarrow d_{shape}(s,t) \leq \varepsilon_{shape}$.
- Color similarity predicates: Given two color representations (c_1,c_2) and a color distance metric d_{color}, the color representations c_1 and c_2 are similar with respect to d_{color} if $d_{color}(c_1,c_2) \leq \varepsilon_{color}$.

Based on the previously defined predicates, several operators are defined: *contains* or *semantic join* (to check whether a salient object is found in an image), the *similarity join* that is used to match two images or two salient objects with respect to a predefined similarity metric on some low-level features (color, texture, shape, etc.), and *spatial join* on physical salient objects:

- Semantic join: Let S be a set of semantic objects of the same type with a behavior *pso* that returns, for a semantic object, the physical salient objects it describes. The *semantic join* between an image class extent I and the semantic object class extent S, denoted by $I \bowtie_{contains} S$, defines the elements of $I \times S$ where for $i \in I$ and $s \in S$, $contains(i,s)$ is true.
- Similarity join: Given a similarity predicate *similar* and a threshold $\in$, the *similarity join* between two sets R and S of images or physical salient objects, denoted by $R \bowtie_{similar(r.i,s.j,\in)} S$ for $r \in R$ and $s \in S$, is the set of elements from $R \times S$ where the behaviors i defined on the elements of R and j on the elements of S return some compatible metric data type T and $similar(r \cdot i, s \cdot j)$ (holds true the behaviors i and j) can be the behaviors that return color, texture, or shape.
- Spatial join: The spatial join of the extent of two sets R and S, denoted by $R \bowtie_{r.i\theta s.j} S$, is the set of elements from $R \times S$ where the behaviors i defined on the elements of R, and j on the elements of S, return some spatial data type, θ is a binary spatial predicate, and $R \cdot i$ stands in relation θ to $S \cdot j$ (θ is a spatial operator like north, west northeast, intersect).

The previously defined predicates and the operators are the basis of the declarative query languages MOQL [67] and Visual MOQL [100]. The DISIMA model was later extended to support video data [25]. MOQL is an extension of the Object Query Language (OQL) [21]. Most extensions introduced to OQL by MOQL involve the where clause, in the form of four new predicate expressions:

spatial expression, temporal expression, contains predicate, and similarity expression. The spatial expression is a spatial extension that includes spatial objects, spatial functions, and spatial predicates. The temporal expression deals with temporal objects, functions, and predicates for videos. The "*contains*" predicate is used to specify the salient objects contained in a given media object. The similarity predicate checks if two media objects are similar with respect to a given metric. Visual MOQL uses the DISIMA model to implement the image facilities of MOQL.

14.4.3 Example of Semistructured Model

MPEG-7, the multimedia content description interface, is an ISO metadata standard defined for the description of multimedia data [44]. The MPEG-7 standard aims at helping with searching, filtering, processing, and customizing multimedia data through specifying its features in a "universal" format. MPEG-7 does not specify any applications, but rather the representation format for the information contained within the multimedia data is represented, thereby supporting descriptions of multimedia made using many different formats. The objectives of MPEG-7 include creation of methods to describe multimedia content, manage data flexibly, and globalize data resources.

MPEG-7 essentially provides two tools: the description definition language (MPEG-7 DDL) [1] for the definition of media schemes and an exhaustive set of media description schemes (DSs) mainly for media low-level features. The predefined media DSs are composed of visual feature descriptor schemes [2], audio feature descriptor schemes [3], and general multimedia DSs [4]. Media description through MPEG-7 is achieved through three main elements: descriptors (Ds), DSs, and a DDL. The descriptors essentially describe a feature or distinctive aspect of the multimedia data. An example of a descriptor would be the camera angle used in a video document. The DS organizes the descriptions, specifying the relationship between descriptors. DSs, for example, would represent how a picture or a movie would be logically ordered. The DDL is used to specify the schemes, as well as to allow modifications and extension to the schemes.

The MPEG-7 DDL is a superset of XML Schema [126], the W3C schema definition language for XML documents. The extensions to XML Schema comprise support for array and matrix data types as well as additional temporal data types. Because MPEG-7 media descriptions are XML documents that conform to the XML Schema definition, it is natural to suggest XML database solutions for the management of MPEG-7 documents, as proposed in [64]. Current XML database solutions are text oriented, and MPEG-7 encodes nontextual data. Directly applying current XML database solutions to MPEG-7 would lower its expressive power, as only textual queries will be allowed.

The models presented in this section are representative of the solutions proposed for multimedia data; however, all have significant limitations. Object or object-relational models assume that multimedia data are well structured, with their content clearly defined. This is not always the case. For example, the content description of an image as it relates to salient objects relies on segmentation and object recognition, both of which are still active research topics. Multimedia content is often represented as a collection of vectors with specific similarity functions, which cannot be represented using the semistructured data models that are commonly applied to text data. Multimedia data are complex data whose representations can involve structured data (multimedia metadata), text (multimedia semantics), as well as vectors (multimedia content). A simple extension of existing data models is not sufficient, especially as the retrieval of multimedia data involves browsing and search as well as classical text-based queries.

14.5 Similarity Search in Multimedia Databases

The aim of a similarity query is to select and return a subset of the database with the greatest resemblance to the query object, all according to a measure of object-to-object similarity or dissimilarity. Data dissimilarity is very commonly measured in terms of distance metrics such as the Euclidean distance, other Lp metrics, the Jaccard distance, or the vector angle distance (equivalent to cosine similarity);

many other measures exist, both metric and nonmetric. The choice of measure generally depends on the types of descriptors used in modeling the data.

Similarity queries are of two main types: range queries and *K*-NN queries. Given a query object $q \in \mathcal{U}$, a data set $S \subseteq \mathcal{U}$, and a distance function d: $\mathcal{U} \times \mathcal{U} \to \mathbb{R}_0^+$, where $\mathcal{U}$ is a data domain, range queries and *K*-NN queries can be characterized as follows:

- Range queries report the set $\{v \in S |\, d(q,v) \leq \varepsilon\}$ for some real value $\varepsilon \geq 0$.
- *K*-NN queries report a set of k objects $W \subseteq S$ satisfying $d(q,u) \leq d(q,v)$ for all $u \in W$ and $v \in S \backslash W$.

Note that a *K*-NN query result is not necessarily unique, whereas a range query result is. Of the two types of similarity queries, *K*-NN queries are arguably more popular, perhaps due to the difficulty faced by the user in deciding a range limit when the similarity values are unknown or when they lack an interpretation meaningful to the user.

Most similarity search strategies seek to reduce the search space directly by means of an index structure. Spatial indices are among the first such structures; a great many examples exist, including *k-d*-trees [12], *B*-trees [11], *R*-trees [46], *X*-trees [13], *SR*-trees [59], and *A*-trees [108]. Such structures explicitly rely on knowledge of the data representation for their organization, which makes them impractical when the representational dimension is very high. Moreover, they usually can handle only queries with respect to Euclidean or other *Lp* distance measures. Later, indices were developed for use with general metric data, such as multi-vantage-point trees [17], geometric near-neighbor access trees (GNAT) [18], and *M*-trees [27]. Unlike spatial indices, metric indices rely solely on pairwise distance values to make their decisions. Many more examples of spatial and metric data structures can be found in [109].

Both spatial and metric search structures do not in general scale well due to an effect known as the curse of dimensionality, so-called due to the tendency of the query performance of indexing structures to degrade as the data dimensionality increases. With respect to a given query item, as the data dimensionality increases, the distribution of distances from a given query object to the data set objects changes: these distances tend to concentrate more tightly around their mean value, leading to a reduction in the ability of the similarity measure to discriminate between relevant and nonrelevant data objects [14]. Evidence shows that as the data dimension approaches 20, the performance of such search structures as the *R**-tree, *SS*-tree, and *SR*-tree typically degrades to that of a sequential scan of the entire data set [14]. However, the dimensionality of multimedia feature vectors is usually much higher than that which can ordinarily be dealt with using spatial or metric indices. For example, color histograms typically span at least 64 dimensions and sometimes many more. Applications using bag-of-words modeling use vectors of many thousands of dimensions to represent the data [141].

More recently, many other approaches have been developed for both exact and approximate *K*-NN search, in an attempt to partially circumvent the curse of dimensionality. For exact search, Koudas et al. [65] proposed a method that used a bitmap data representation to facilitate the search process. Jagadish et al. [57] developed iDistance, in which high-dimensional objects are transformed into 1D values, which are then indexed for *K*-NN search using a *B*+-tree. Beygelzimer et al. [15] introduced the cover tree index, in which the search is performed by identifying a set of nodes whose descendants are guaranteed to include all nearest neighbors.

For approximate search, Andoni et al. [7] developed the MedScore technique, in which the original high-dimensional feature space is transformed into a low-dimensional feature space by means of random projections. For each dimension in the new feature space, a sorted list is created. The search is done by aggregating these sorted lists to find the objects with the minimum median scores. The well-known threshold algorithm [40] is used here for the aggregation. Indyk and Motwani [55] proposed a popular hashing-based search framework called LSH, in which pairs of similar objects have higher probabilities of mapping to the same hash location than pairs of dissimilar objects. Many variants and improvements upon LSH have subsequently been proposed, such as spectral hashing [131], where the hash bits are determined by thresholding a subset of eigenvectors of the Laplacian of the similarity graph on the data objects.

All of these recently proposed methods attempt to improve upon the performance of their predecessors on high-dimensional data, through the use of domain reduction techniques: via the direct reduction of either the data set (sampling) or attribute set (projection) or via hashing or other data domain transformations. Generally speaking, these methods can cope with data of up to several hundred dimensions before succumbing to the effects of the curse of dimensionality. Further improvements in performance can then be sought through the use of parallelism, as is possible using MapReduce [30], or other forms of distributed processing [9]. Ensembles of similarity indices have also been considered. The fast library for approximate nearest neighbors (FLANN) uses an ensemble of randomized k-d-tree indices [116] and hierarchical K-means trees [94], along with automatic parameter tuning of these indices for optimized performance [90]. It has been shown to achieve very good practical performance for many data sets with up to approximately 200 dimensions.

Recent advances have been made as to the indexability of multimedia data sets of very large scale, in both data set size and data set dimensionality. For data sets of extreme size, a product quantization-based approach for approximate nearest neighbor search has recently been developed that has been successfully applied to the indexing of two billion SIFT vectors of dimension 128, taken from a set of one million images [58]. After decomposing the space into a Cartesian product of low-dimensional subspaces, each subspace is quantized separately. The Euclidean distance between two vectors can be efficiently estimated from short codes composed of the vectors' quantization indices. Inverted list techniques are then used to assemble a final query result.

For data sets of extreme dimensionality, Houle and Sakuma [51] proposed an approximate search index called a spatial approximation sample hierarchy (SASH), a multilevel structure recursively constructed by building a SASH on a large random data sample and then connecting the remaining objects to several of their approximate nearest neighbors from within the samples. For lower-dimensional data (on the order of 200 dimensions or less), the overheads associated with their sampling strategy generally render the SASH index less competitive than ensemble methods such as FLANN [90] or the heavily optimized product quantization method of [58]. However, the use of near neighbors for distance discrimination can often overcome the effects of the curse of dimensionality for sparse data sets of extremely high dimension (with both the number of vectors and the dimensionality in the millions), as sometimes arise in applications where the data are modeled using the bag-of-words representation.

14.6 Conclusion

In this chapter, we have surveyed multimedia databases in terms of data analysis, data querying, and indexing. In multimedia databases, raw multimedia data are unfortunately of limited use due to its large size and lack of interpretability. Consequently, they are usually coupled with descriptive data (including both low-level features and mid- to high-level semantic information) obtained by analyzing the raw media data. Various types of features and concepts related to image, video, and audio data are thus required along with some popular techniques for extracting them. Some latest work on integrating multiple media modalities to better capture media semantics has also been reviewed.

Retrieving a specific image, video, or song that a user has in mind remains a challenging task. Currently, the search relies more on metadata (structured data or textual description) than on the media content. The general problem with images and videos is that their digital representations do not convey any meaningful information about their content. Often to allow semantic search, an interpretation must be added to the raw data, either manually or automatically. Manual annotation of images and video is tedious, and automatic inference of the semantics of images and videos is not always accurate. Multimedia data annotation is still an active research topic, and existing approaches motivate users either to annotate images by simplifying the procedure [35,107,129] or to annotate images in an automatic or semiautomatic way [50,123,132]. In [115], Flickr generates candidate tag lists derived from user-defined tags of each image by computing tag co-occurrence and then recommending new tags by aggregating and ranking the candidates. The ideal solution in which the user does not intervene or manually annotates objects of interest is yet to be proposed.

A related and pressing issue is the lack of a complete data model for multimedia data. Although the idea of extending existing multimedia data models is an appealing one, models defined for classical data cannot effectively handle multimedia data. Metadata such as names, dates, and locations can indeed be stored in a relational database; however, for other types, a relational database does not suffice. For example, the content of an image can also be described using text, and high-dimensional vectors can be described using SIFT descriptors. Across differing real-life applications, different media types are used to describe the same information. This is the case for news applications, where an individual event can be covered by TV channels using video, by radio stations using audio, and by newspapers using text and images. Any successful multimedia data model must be sufficiently general so as to be able to address each of these issues.

Building Conceptual Modeling on the Foundation of Ontology

Andrew Burton-Jones
The University of Queensland

Ron Weber
Monash University

15.1 Introduction

Conceptual models provide a representation, often graphical, of some features of a real-world domain. Frequently, information system professionals (e.g., system analysts) prepare these models to achieve two outcomes (e.g., Fettke, 2009). First, during the system development process, conceptual models facilitate communications among stakeholders. For instance, they may be used by analysts to check their understanding of the domain to be supported by the system being developed with likely users of the system. Second, after a system has been implemented, conceptual models assist users of the system or information systems professionals who must maintain and operate the system to undertake their work. For instance, they may be employed by managers to help formulate queries to interrogate the system's database or programmers to understand the system so they can undertake maintenance work.

Conceptual models are generated using some kind of conceptual modeling technique. For instance, an early technique was entity–relationship modeling (Chen, 1976), which provided its users with three constructs—entities, relationships, and attributes—to represent real-world phenomena that were of interest to them. When entity–relationship modeling is used, any real-world phenomenon of interest has to be mapped to one of these three constructs. Figure 15.1 shows an entity–relationship model of a simple domain.

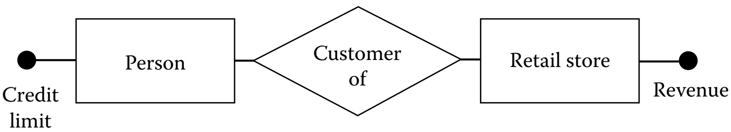

FIGURE 15.1 Simple entity–relationship model.

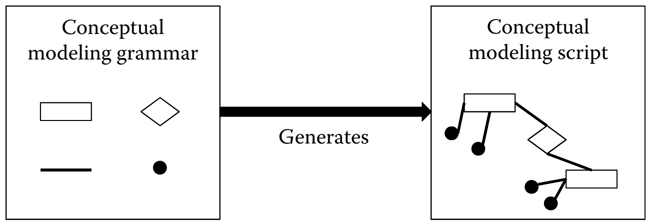

FIGURE 15.2 Generating conceptual modeling scripts via a conceptual modeling grammar.

More formally, a conceptual modeling technique can be conceived as a type of *grammar* that is used to generate *scripts* (Figure 15.2) (Wand and Weber, 1993). The conceptual modeling grammar provides various constructs to model different types of phenomena in the real world. The scripts generated via the grammar contain strings of *instances* of constructs in the grammar. These instances provide representations of specific real-world phenomena that are of interest to stakeholders in the system.

Historically, many different conceptual modeling techniques have been proposed. Indeed, at one stage of their development, the term "YAMA" was coined (Oei et al., 1992, p. 2), which stood for "yet another modeling approach." This term manifested the frustration many researchers felt at the time with the proliferation of existing modeling techniques, the ongoing emergence of still more techniques, and the paucity of rigorous research that evaluated their relative strengths and weaknesses. Moreover, the tendency of researchers and practitioners to propose new techniques *without* strong theory or empirical evaluation remains:

> "Even though hundreds of modelling methods are in existence today, practitioners and researchers are zealously 'producing' new modelling methods. … Many of these methods lack theoretical foundations and empirical evidence to demonstrate their worthiness" (Siau and Rossi, 2011, p. 249).

The conceptual modeling techniques that have been proposed over the years tend to fall into one of two categories. The first category primarily provides constructs to model *substance and form* in the real world—specifically, things and their properties (including how things are associated with other things and how properties of things are related). These techniques are often called "data modeling techniques" or "semantic modeling techniques." Contrary to their name, however, often they are *not* used to model "data" in the real world. Instead, they are used to model certain real-world phenomena directly rather than the data that in turn might be chosen to represent the phenomena. Moreover, while the techniques can be used to model certain real-world semantics, they are capable of modeling only a *subset* of the real-world semantics that might interest stakeholders.

The second category of conceptual modeling techniques that have been developed primarily provides constructs to model *possibility and change* in the real world—specifically, the state spaces and event spaces that things in the real world might traverse and the transformations these things might undergo. These techniques are often called "process modeling techniques." This name is more appropriate than the names chosen for the first category of techniques. Process modeling techniques indeed provide constructs to model how changes occur in a domain.

Interestingly, historically few conceptual modeling techniques have been proposed that have a comprehensive focus on *both* substance and form as well as possibility and change. The reasons are unclear.

The so-called data or semantic modeling techniques developed first, perhaps because early designers of conceptual modeling techniques found the real-world semantics of substance and form easier to understand and thus simpler to model. Process modeling techniques developed somewhat later, perhaps because designers of conceptual modeling techniques found the real-world semantics of possibility and change harder to understand and thus more difficult to model. Moreover, historically data and semantic modeling techniques have been linked with database development, whereas process modeling techniques have been linked with application development. A recent trend is to advocate using *collections* of techniques to overcome the limitations of individual techniques. For instance, the unified modeling language (UML) includes some techniques more focused on substance and form (such as class diagrams) and other techniques more focused on possibilities and change (such as activity diagrams and statecharts) (Rumbaugh et al., 1999).

Motivated by the importance of conceptual modeling and the lack of theory and evidence to inform conceptual modeling practice, in the late 1980s, Wand and Weber began to develop an approach to evaluating conceptual modeling techniques that relied on the philosophical field of ontology* (e.g., Wand and Weber, 1993, 1995). This approach was an innovation at that time because previously conceptual modeling researchers and practitioners had not relied on theories of ontology. Wand and Weber noted that ontological researchers are concerned with building theories about the nature of existence—that is, theories about the nature of the fundamental types of phenomena that occur in the real world. Furthermore, they noted that, in essence, conceptual modelers are also concerned with building models of some subset of phenomena in the real world. Specifically, their work can be conceived as developing *specialized ontologies*—models of a particular domain in the real world.

Given that philosophical researchers had been working on theories of ontology for many hundreds of years, Wand and Weber believed these theories could be used to inform evaluations of the quality of both conceptual modeling grammars and conceptual modeling scripts. Specifically, they argued that ontological theories could be used to make predictions about the strengths and weaknesses of conceptual modeling grammars and scripts. These predictions could then be tested empirically.

Wand and Weber's proposed approach differed substantially from previous approaches used to evaluate conceptual modeling grammars and scripts. These prior approaches had relied primarily on case studies in which different conceptual modeling techniques were used to model some domain (e.g., Floyd, 1986). The strengths and weaknesses of the resulting models were then compared. Unfortunately, the case study approach often proved unsatisfactory as a way of resolving disputes. For instance, one group of protagonists inevitably made allegations that the case study chosen had been selected deliberately to downplay the strengths and highlight the weaknesses of the particular technique they favored. In the absence of theory, it was difficult to see how disputes might be resolved.

Building conceptual modeling on the foundation of ontology is now an accepted approach in the conceptual modeling field (Siau and Rossi, 2011). The purpose of this chapter, therefore, is to provide an overview of this approach, describe two theories used by researchers that are based on ontology, and illustrate the kinds of the results that have emerged from empirical investigations of these theories. We first discuss the underlying principles that have motivated theoretical analyses of and empirical research on conceptual modeling practice. Next, we describe some examples of the research done (based on these principles) and how the findings have implications for conceptual modeling practice. Subsequently, we consider some significant research opportunities that exist in the application of ontological principles to conceptual modeling practice. Finally, we present a brief summary of our analyses and some conclusions.

* Unfortunately, the term "ontology" now has multiple meanings in the information technology literature. It is sometimes used as the generic term that refers to the branch of philosophy that deals with the nature of existence in the real world. It is also used to refer to a particular scholar's theory about the nature of existence in the real world (e.g., Bunge's, 1977, 1979 ontology). More recently, it is sometimes used to refer to a description of a particular domain.

15.2 Underlying Principles

The idea that conceptual modelers in essence are building specialized ontologies motivates the conclusion that the modeling grammars they use must therefore be capable of representing the major types of phenomena that exist in the real world. This conclusion has underpinned the development of two theories about conceptual modeling grammars—one to account for the strengths and weaknesses of individual grammars and the other to account for how multiple grammars might be selected for conceptual modeling purposes. The following two subsections explain the nature and uses of both theories.

15.2.1 Theory of Ontological Expressiveness

The foundation for much ontologically based work on conceptual modeling is Wand and Weber's (1993) *theory of ontological expressiveness* (TOE). The TOE was formulated to address the question of how well conceptual modeling grammars are able to model real-world phenomena.

TOE is based upon a mapping between two sets of constructs: (1) a set of ontological constructs developed to describe various phenomena in the real world and (2) a set of grammatical constructs developed to generate "scripts" that describe various phenomena in the real world. The ontological constructs should be derived from a coherent theory about the nature and form of phenomena in the real world. The grammatical constructs should be derived from a careful specification of the grammar's capabilities.

Wand and Weber propose a conceptual modeling grammar that is *ontologically expressive* when the mapping between ontological constructs and grammatical constructs is one-to-one and onto (isomorphic)—that is, each and every ontological construct maps to one and only one grammatical construct, and each and every grammatical construct is the "image" (or representation) of one and only one ontological construct. Effective visual reasoning with software engineering notations also seems to depend on having an isomorphic mapping between semantic constructs and visual symbols (syntax) (Moody, 2009, pp. 762–763).

In TOE, an isomorphic pattern exists when four conditions hold (Figure 15.3):

1. Each ontological construct maps to one and only one grammatical construct.
2. Each grammatical construct maps to one and only one ontological construct.

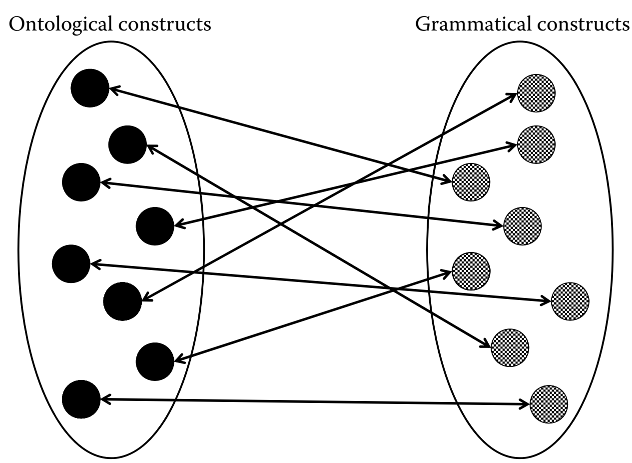

FIGURE 15.3 An ontologically expressive conceptual modeling grammar.

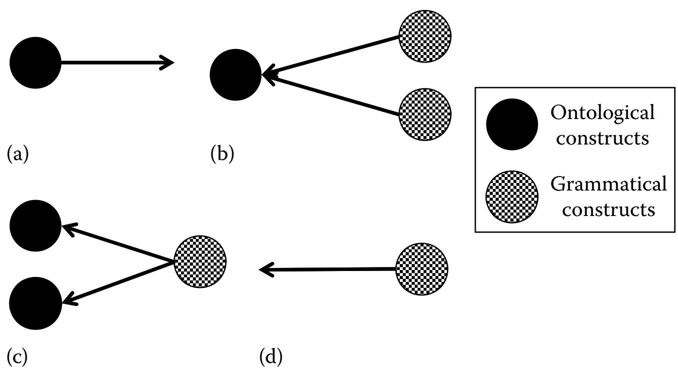

FIGURE 15.4 Factors that undermine the ontological expressiveness of a conceptual modeling grammar. (a) Construct deficit, (b) construct redundancy, (c) construct overload, and (d) construct excess.

3. All ontological constructs are "covered" by a grammatical construct—in other words, every ontological construct maps to a grammatical construct.
4. All grammatical constructs are "covered" by an ontological construct—in other words, every grammatical construct maps to an ontological construct.

When a mapping is undertaken between the two sets of constructs, four situations can arise that Wand and Weber argue undermine the ontological expressiveness of a conceptual modeling grammar (Figure 15.4). The first situation—construct deficit—undermines the *ontological completeness* of a modeling grammar. The next three situations—construct redundancy, construct overload, and construct excess—undermine the *ontological clarity* of a grammar. The four situations are defined as follows:

1. *Construct deficit*: Construct deficit arises when no grammatical construct exists that maps to a particular ontological construct. The consequence is that some aspect of the real world cannot be represented in scripts generated using the grammar.
2. *Construct redundancy*: Construct redundancy arises when two or more grammatical constructs map to a single ontological construct (m:1 mapping). The consequence is that different grammatical constructs can be used to represent the same real-world phenomenon. As a result, users of a script may become confused about what instances of the grammatical constructs represent when they try to interpret a script. They may try to interpret a script using the assumption that instances of different grammatical constructs are meant to represent different types of real-world phenomena.
3. *Construct overload*: Construct overload arises when a grammatical construct maps to two or more ontological constructs (1:m mapping). The consequence is that users of a script may be unable to understand the meaning of a real-world phenomenon represented by an instance of the construct.
4. *Construct excess*: Construct excess arises when a grammatical construct exists that does not correspond to any ontological construct. The consequence is that users of a script may be unable to understand what an instance of the construct is intended to represent.

Figure 15.5 provides an overview of TOE. It shows that user task effectiveness and efficiency will be higher when a modeling grammar has higher levels of ontological expressiveness. The level of a grammar's ontological expressiveness will be higher when it has lower levels of ontological deficit and higher levels of ontological clarity. Its ontological clarity will be undermined when it has higher levels of construct redundancy, overload, and excess.

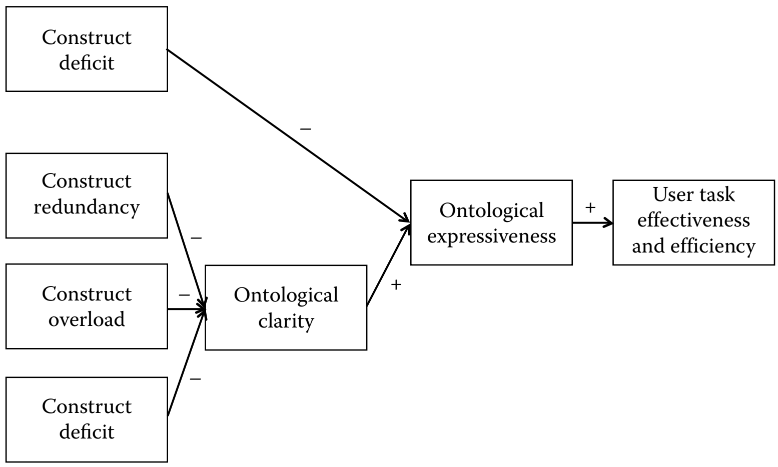

FIGURE 15.5 Theory of ontological expressiveness (TOE).

Ontological completeness and clarity are relative concepts. In other words, whether a conceptual modeling grammar is deemed ontologically complete and/or clear depends on the particular ontology used to undertake the evaluation (the "reference" ontology). For instance, some ontologies make a distinction between "things" and "properties of things" (e.g., Bunge, 1977). Others make no such distinction and have only the concept of an "entity" or "thing" (e.g., Cocchiarella, 1972). A conceptual modeling grammar that provides only a single construct to model both "things" and "properties of things" will be *ontologically unclear* under the former ontology. (It will possess ontological overload because a single grammatical construct maps to two ontological constructs.) It will be ontologically clear, however, under the latter ontology.

Similarly, an ontology may have a single construct to represent the real-world phenomenon of an event. A conceptual modeling grammar may have several constructs, however, to represent different *types* of events (e.g., initial events, intermediate events, and final events). Providing the real-world meanings of the different event constructs in the modeling grammar do not overlap, the grammar does *not* have construct redundancy. Rather, it is based on a more specialized ontology than the ontology used to undertake the evaluation for completeness and clarity.

Whether ontological completeness and clarity (or lack thereof) have any practical impact is an empirical issue (Gemino and Wand, 2005, p. 307). Predictions about the effects of an ontologically complete and clear grammar or an ontologically incomplete or unclear grammar need to be tested in the context of users' performance with scripts generated via the grammar. For instance, a conceptual modeling grammar might be deemed ontologically unclear because it provides only a single construct to represent "things" and "properties of things." Nonetheless, lack of ontological clarity has no import unless the performance of stakeholders who engage with the grammar or scripts generated via the grammar is undermined in some way. Similarly, the performance of stakeholders who engage with an ontologically clear conceptual modeling grammar might be poor because the ontology used to evaluate ontological clarity is deficient.

15.2.2 Theory of Multiple Grammar Selection

Because stakeholders often engage with conceptual modeling grammars that have construct deficit, they may conclude they must use multiple grammars to meet their modeling needs. Based on TOE, Green (1996) proposed a theory to account for how stakeholders will select the grammars to use from a set of

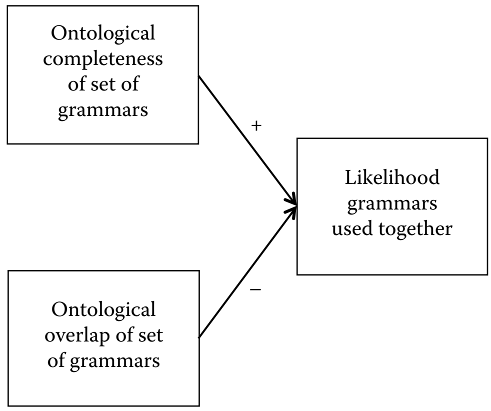

FIGURE 15.6 Theory of multiple grammar selection (TMGS).

alternatives—the theory of multiple grammar selection (TMGS) (Figure 15.6). He proposed that stakeholders will seek to satisfy two objectives:

1. *Maximum ontological coverage (MOC)*: Stakeholders will choose a combination of grammars to afford them maximum coverage of the phenomena they wish to model. In other words, they will seek to minimize problems caused by construct deficit.
2. *Minimum ontological overlap (MOO)*: Stakeholders will choose a combination of grammars to afford them minimum ontological redundancy. In other words, they will seek to mitigate problems arising from having multiple grammatical constructs covering the same ontological construct.

Green argued the primary objective in selecting a combination of modeling grammars is to achieve MOC. This objective has to be moderated, however, by problems that might arise as the level of ontological overlap among the grammars increases. Moreover, he argued stakeholders will seek to achieve parsimony in their selection of grammars. They will select the smallest number of grammars that allow them to achieve their MOC and MOO objectives satisfactorily.

Mindful of the MOC and MOO objectives, Green et al. (2007) and zur Muehlen and Indulska (2010) have proposed five metrics to evaluate when selecting a combination of modeling grammars to use. In the context of two grammars, G_1 and G_2, these metrics are based on the following sets:

- *Union of ontological constructs in G_1 and G_2: $G_1 \cup G_2 = x \in G_1 \vee x \in G_2$*: The number of elements in this set is the number of ontological constructs that can be represented by using *both* modeling grammars. Ideally, this number will equal the number of constructs in the reference ontology.
- *Symmetric difference of ontological constructs covered in G_1 and G_2: $G_1 \Delta G_2 = (G_1 - G_2) \cup (G_2 - G_1)$*: The number of elements in this set is the number of constructs in the reference ontology that G_1 and G_2 represent *distinctly* (i.e., free from overlap). Relative to the number of constructs in the reference ontology, ideally the number in the symmetric difference will be *large* (thereby indicating little overlap exists in the ontological constructs covered by the two grammars).
- *Intersection of ontological constructs covered in G_1 and G_2: $G_1 \cap G_2 = x \in G_1 \wedge x \in G_2$*: The number of elements in this set is the number of ontological constructs that can be represented in *both* modeling grammars. Relative to the number of constructs in the reference ontology, ideally the number in the intersection will be *small* (thereby indicating little overlap exists in the ontological constructs covered by the two grammars).
- *Difference of ontological constructs covered in G_1 and G_2: $G_1 - G_2 = x \in G_1 \wedge x \notin G_2$*: The number of elements in this set is the number of additional (nonoverlapping) ontological constructs that can be represented in modeling grammar G_1 (i.e., the constructs cannot be represented in

modeling grammar G_2). Ideally, this number will be large, thereby indicating G_1 adds substantially to G_2's ontological coverage.

- *Difference in ontological constructs covered in* G_2 *and* G_1: $G_2 - G_1 = x \in G_2 \wedge x \notin G_1$: The number of elements in this set is the number of additional (nonoverlapping) ontological constructs that can be represented in modeling grammar G_2 (i.e., the constructs cannot be represented in modeling grammar G_1). Ideally, this number will be large, thereby indicating G_2 adds substantially to G_1's ontological coverage.

Note the last four metrics all provide a slightly different perspective on the extent to which ontological overlap exists between the two grammars. The different perspectives may prove helpful, however, in appraising the merits of using two grammars in combination.

15.3 Impact on Practice

The two theories we have outlined (TOE and TMGS) essentially stem from the same general argument, which is that the ontological "quality" of a grammar or grammars affects the use of, or consequences of using, the grammar or grammars. While the outcome construct in TOE concerns the consequences of using grammars (see Figure 15.5), second-order consequences might arise (e.g., poor system design). Likewise, while the outcome construct in TMGS concerns the selection of grammars (see Figure 15.6), the guiding logic is that people will choose to use grammars that yield beneficial consequences. Some of the literature we review in this section makes precisely such predictions.

According to Moody (2005), most conceptual modeling techniques have had little impact on practice. As a result, the purpose of developing theories such as TOE and TMGS is to help stakeholders in the conceptual modeling community explain and predict the use and consequences of using conceptual modeling techniques in practice. In this vein, we subscribe to a view, often attributed to Lewin (1945), that "nothing is quite so practical as a good theory."

> Lewin's [view]…is as important today as it was in Lewin's time. Good theory is practical precisely because it advances knowledge in a scientific discipline, guides research toward crucial questions, and enlightens the profession… (Van de Ven, 1989, p. 486).

As noted earlier, TOE and TMGS are ontology-agnostic. Nevertheless, in this section, we examine how both theories have been used with a *particular* theory of ontology—namely, Bunge's (1977) theory of ontology—to derive predictions about and recommendations for conceptual modeling practice. We have chosen Bunge's theory of ontology because for two reasons it has informed much ontologically based conceptual modeling research*: (a) it has been articulated carefully and formally; and (b) it uses constructs employed widely within the information technology field.

To show how Bunge's theory of ontology can be used in conjunction with TOE and TMGS to inform conceptual modeling practice, we describe examples of research studies that have first derived analytical results and then evaluated these results empirically. We have chosen these studies because, like Moody (2005) and Siau and Rossi (2011), we believe empirical results add weight to analytical results. Nonetheless, the results obtained from the combined analytical and empirical studies mirror those obtained from the purely analytical studies—for instance, analytical studies of the ontological expressiveness of the entity–relationship grammar (Wand and Weber, 1993), UML grammar (Evermann and Wand, 2005a,b), NIAM grammar (Weber and Zhang, 1996), object-modeling grammar (Opdahl and Henderson-Sellers, 2004), and ARIS grammar (Fettke and Loos, 2007), and the ways in which various process modeling and rule modeling grammars should be used in conjunction with one another (zur Muehlen and Indulska, 2010).

* We reference some of this research in the sections and subsections that follow.

In the following two subsections, note we have not sought to provide a comprehensive review of prior studies. Rather, our goal is to illustrate how Bunge's theory of ontology, TOE, and TMGS have been employed in prior research to derive outcomes that can be used to inform practice.

15.3.1 Conceptual Modeling Practice and the TOE

Several research studies have now been conducted that use TOE and Bunge's theory of ontology as the reference ontology to make predictions about the strengths and weaknesses of different conceptual modeling grammars and to test these predictions empirically. Based on the results obtained, some conclusions can be drawn for conceptual modeling practice.

15.3.1.1 Construct Deficit

Recall, construct deficit arises in a conceptual modeling grammar when a construct exists in the reference ontology for which no corresponding construct exists in the grammar. In the presence of construct deficit, TOE motivates a prediction that instances of real-world phenomena represented by instances of the ontological construct cannot be represented in scripts generated via the grammar. The outcome is that the scripts provide an incomplete description of the real-world domain of interest.

Recker et al. (2009) studied 12 process modeling grammars (ANSI flowcharts, data flow diagrams, IDEF method 3 process description capture method, ISO/TC97, Merise, EPC, BPML, WSCI, ebXML, WS-BPEL, Petri nets, and BPMN) from the perspective of ontological completeness and clarity. As their reference ontology, they used the so-called Bunge–Wand–Weber (BWW) ontology, which is an extension and adaptation of Bunge's theory of ontology by Wand and Weber (1990).*

In terms of ontological completeness, they found all the grammars had construct deficit according to the BWW ontology. As a measure of construct deficit, for each grammar, they counted the number of constructs in the BWW ontology that were not covered by a grammatical construct and divided this number by the total number of constructs defined in the BWW ontology. The average measure of construct deficit across the 12 grammars was 59.21% (the range was 9.10%–81.80%). In other words, on average, approximately 59% of the constructs in the BWW ontology could not be represented via constructs in the grammars.

In light of their analysis, Recker et al. (2009) predicted users of the grammars they studied would encounter a number of difficulties. For instance, they concluded

- Good process decompositions could not always be achieved because some of the grammars had no constructs to model phenomena such as things, classes of things, and properties of things, which are needed to design good decompositions (Burton-Jones and Meso, 2006).
- Some of the grammars had no constructs to model lawful and conceivable state spaces. As a result, they provided limited support for the identification of unlawful states and the design of exception handling processes.
- The ability to define and refine business rules was limited because some of the grammars had no constructs to model the history of things (and thus the sequence of states things traversed).
- Most of the grammars had no constructs to model the environment of a system. As a result, the process models they could represent were decoupled from their environment. The design of context-aware process models became difficult, if not impossible.

Recker et al. (2011) then undertook a web-based survey of users' experiences with one of the grammars they analyzed—namely, BPMN. They chose BPMN because it is used extensively to undertake business process modeling. In their survey instrument, they asked BPMN users about the extent to which they perceived BPMN has certain kinds of construct deficit (e.g., "BPMN does not provide sufficient symbols to represent business rules in process models").

* Wand and Weber (1990) sought to show how Bunge's (1977) theory of ontology could be applied to the information technology domain, to extend Bunge's theory to include additional constructs that were useful in the information technology domain, and to correct certain errors that they believed existed in Bunge's theory.

Recker et al. (2011) obtained 528 usable responses from BPMN users around the world. They found a negative association between the extent to which these users perceived BPMN had certain kinds of construct deficit (based on their experience with BPMN) and the extent to which they perceived BPMN was *useful* in achieving their modeling objectives. Moreover, Recker et al. (2011) found these users' perceptions of BPMN's usefulness declined as a function of the number of different types of construct deficit they had encountered.

Recker et al. (2010) also interviewed 19 business process modeling practitioners in six Australian organizations about their experiences with BPMN. Again, they tested the extent to which construct deficit in BPMN undermined these practitioners' work. As with their survey results, for the most part they found the forms of construct deficit they investigated caused difficulties for the practitioners in the work they undertook.

When considering the acquisition of a grammar for conceptual modeling purposes, practitioners can use Bunge's theory of ontology and TOE to analyze the grammar for construct deficit. To the extent egregious instances of construct deficit exist in the candidate grammar, other grammars should be considered as alternatives. In some cases, practitioners may be unable to find a single grammar that covers the ontological constructs important to their modeling needs. As a result, multiple grammars might be chosen that provide *complementary* capabilities. In other words, the grammars are selected so that constructs that are missing in one grammar will be present (covered by) in another grammar. The recognition that multiple modeling grammars are needed to address construct deficit problems that practitioners confront motivated the articulation of the TMGS (which we discuss further in the subsequent sections).

15.3.1.2 Construct Redundancy

Recall, construct redundancy arises in a conceptual modeling grammar when two or more constructs in the grammar map to a single construct in the reference ontology. In the presence of construct redundancy, TOE motivates a prediction that users of the grammar will encounter difficulties when they have to make decisions about which of the redundant constructs to choose in modeling an instance of the ontological phenomenon in the real world. Moreover, stakeholders who have to interpret scripts that contain instances of the redundant constructs will encounter difficulties interpreting the meaning of instances of the constructs.

In their study of 12 process modeling grammars (see preceding text), Recker et al. (2009) were able to assess the level of construct redundancy in *seven* of the grammars they examined—namely, EPC, BPML, WSCI, ebXML, WS-BPEL, Petri nets, and BPMN. They measured construct redundancy by counting the number of redundant grammatical constructs (based on the BWW ontology) and dividing this number by the total number of constructs in the grammar. The average measure of construct redundancy across the seven grammars was 26.93% (the range was 0%–51.30%). In other words, on average, approximately 27% of the constructs in the grammars were redundant.

In light of their analysis, Recker et al. (2009) predicted users of the grammars they studied would encounter a number of difficulties. For instance, they concluded

- For some of the grammars, the high level of construct redundancy that existed in relation to several ontological constructs was likely to cause confusion among users of the grammars.
- Construct redundancy in the grammars sometimes seemed to have occurred because of specialization (subtyping) of a BWW ontological construct. The motivation for the specialization appeared to have been particular objectives that designers of the grammars were seeking to achieve (e.g., assisting users to undertake validation of scripts generated using the grammar). Whether such specializations were likely to be successful was unclear.
- Some types of construct redundancy appeared to represent variations on the same ontological construct with the goal of better meeting the needs of different user communities who have different process modeling purposes (e.g., compliance management versus enterprise systems configuration).

In data obtained from their web-based survey of global BPMN users (see preceding text), Recker et al. (2011) found a negative association between the extent to which these users perceived BPMN had certain kinds of construct redundancy (e.g., "I often have to choose between a number of BPMN symbols to represent one kind of real-world object in a process model") and the extent to which they perceived BPMN was *easy to use*. They also found these users' perceptions of BPMN's ease of use declined as a function of the number of different types of construct redundancy they had encountered.

Based on interview responses obtained from 19 business process modeling practitioners in six Australian organizations (see preceding text), however, Recker et al. (2010) found the existence of construct redundancy in BPMN for the most part did *not* undermine the practitioners' work. While the practitioners recognized construct redundancy existed in BPMN, they found ways to mitigate its effects. For instance, one way in which users of process modeling grammars cope with construct redundancy is to confine their use of the grammar to certain constructs and not others (zur Muehlen and Recker, 2008).

In short, based on Recker et al.'s (2009) study, the evidence about the impact of construct redundancy on the users of conceptual modeling grammars is mixed. Nonetheless, there is a straightforward way in which stakeholders might seek to cope with problems that might arise from construct redundancy in a conceptual modeling grammar. Specifically, they can choose to use only one of the redundant constructs associated with a particular ontological construct and proscribe use of the other redundant construct(s).

15.3.1.3 Construct Overload

Recall, construct overload arises in a conceptual modeling grammar when a grammatical construct maps to two or more constructs in the reference ontology. In the presence of construct overload, TOE motivates a prediction that users of the grammar will encounter difficulties when they have to make decisions about how to model instances of the different ontological constructs. Moreover, stakeholders who have to interpret scripts that contain instances of the overloaded construct may fail to notice important differences in the meaning of different instances of the overloaded construct. They may also encounter difficulties interpreting the meaning of different instances of the overloaded construct.

Not all conceptual modeling grammars provide separate constructs to model classes of things (entities) and properties (attributes) in general of these classes of things. For instance, the object role modeling (ORM) grammar uses only a single construct (an entity, shown graphically via a named ellipse or rounded rectangle) to represent both things and properties (Halpin, 2008). Interestingly, users of ORM are told to focus on "facts," which are stated in terms of *objects* having *properties* or multiple objects participating in a *relationship*. In the scripts generated via ORM, however, objects and properties are both represented using the same grammatical construct. For instance, Figure 15.7 shows an ORM script in which two entities (warehouse and inventory) and two attributes of these entities (inventory item name and retail price of inventory item) are all represented by named ellipses.

Bunge's theory of ontology sustains a clear distinction between "things" and "properties of things." In the context of TOE, therefore, ORM has construct overload because a single grammatical construct (an ellipse) is used to represent two ontological constructs—namely, classes of things and properties in general of classes of things. As a result, the theory motivates a prediction that users of ORM scripts will become confused when they have to interpret instances of ellipse constructs in the scripts.

Weber (1996) provides evidence to suggest the organization of human memory relies on a distinction being sustained between "things" and "properties of things." He undertook a multi-trial free-recall experiment in which participants where first shown NIAM diagrams (NIAM is an earlier version of ORM). Participants were then asked to recall the diagrams once the diagrams were removed. Across multiple trials of the experiment, participants' recall protocols indicated they had a propensity to recall ellipses that designated "things" first followed by ellipses that designated "properties of things." Moreover, having recalled a "thing" ellipse, they then recalled ellipses that designated "properties of things" in clusters where the clusters related to the thing they had first recalled. In light of his experimental results,

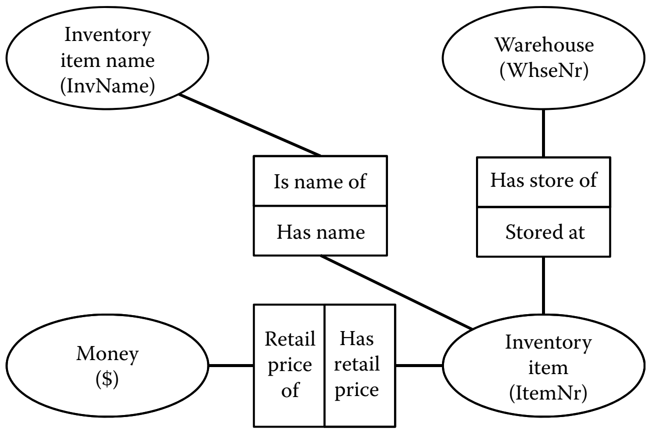

FIGURE 15.7 Object role model of a simple domain.

Weber (1996) concluded users of NIAM diagrams imposed a structure of "things" and "properties of things" on the diagrams even though this structure was not represented explicitly in the diagrams. In short, his results supported the proposition that the object construct in ORM was overloaded because it represented both a class of things and a property in general of a class of things.

In subsequent research, Shanks et al. (2010) conducted an experiment in which the participants were 80 individuals who had work experience but little or no experience with conceptual models. The participants were presented with four different versions of an entity–relationship model of a sales order domain. Based on Bunge's (1977) ontology, the first version used three different grammatical constructs to represent classes of things, mutual properties in general, and intrinsic properties in general. The second version represented classes of things and mutual properties in general via the same grammatical construct (an entity), but it still represented intrinsic properties in general via a different grammatical construct (an attribute). The third version represented classes of things, mutual properties in general, and some intrinsic properties in general (but not all) via the same grammatical construct (an entity). The fourth version represented all classes of things, mutual properties in general, and intrinsic properties in general via a single grammatical construct (an entity). Thus, the four versions of the conceptual model contained increasing levels of construct overload.

Shanks et al. (2010) had four different groups of participants perform three tasks: answer comprehension questions about the domain; solve problems relating to the domain; and check the correspondence of the conceptual model to a textual description of the domain. They found performance differences for the comprehension task but not the problem-solving and discrepancy-testing tasks. In particular, participants who received the conceptual model that showed a clear distinction between classes of things, mutual properties in general, and intrinsic properties in general outperformed participants who received the conceptual model that did not maintain a distinction among these three constructs. Similar results were then obtained in a protocol study that Shanks et al. (2010) undertook with 12 participants, all of whom had at least 3 years' industry experience. Again, the entity construct caused problems for participants when it was overloaded.

In their study of 12 process modeling grammars (see preceding text), Recker et al. (2009) were able to assess the level of construct overload in *seven* of the grammars they examined—namely, EPC, BPML, WSCI, ebXML, WS-BPEL, Petri nets, and BPMN. They measured construct overload by counting the number of grammatical constructs that mapped to more than one BWW construct and dividing this number by the total number of constructs in the grammar. The average measure of construct overload across the seven grammars was 15.04% (the range was 0%–42.90%). In other words, on average, approximately 15% of the constructs in the grammars mapped to more than one ontological construct.

In light of their analysis of construct overload, Recker et al. (2009) predicted users of the grammars they studied would encounter a number of difficulties. For instance, they concluded

- Some grammars achieve higher levels of ontological completeness only by allowing their constructs to be overloaded. Prior research on process models suggests, however, that the benefits of ontological completeness are quickly undermined when the meaning of instances of overloaded constructs is difficult to interpret.
- Use of an overloaded construct often requires process modelers to provide additional explanations to assist readers of process models to interpret the meaning of instances of the construct. As a result, any benefits from allowing more modeling flexibility via overloaded constructs dissipate quickly.

In data obtained from their web-based survey of global BPMN users (see preceding text), Recker et al. (2011) found a negative association between the extent to which these users perceived BPMN had certain kinds of construct overload (e.g., "I often have to provide additional information to clarify the context in which I want to use the Pool symbol in a process model") and the extent to which they perceived BPMN was *easy to use*. They also found these users' perceptions of BPMN's ease of use declined as a function of the number of different types of construct overload they encountered.

In their interviews with 19 business process modeling practitioners in six Australian organizations (see preceding text), Recker et al. (2010) also found the existence of construct overload in BPMN undermined the work on these practitioners. The practitioners confirmed the real-world meaning of the overloaded constructs was unclear. As a result, the overloaded constructs were often used inconsistently in the business process models they encountered.

One way in which stakeholders might seek to cope with problems that arise from construct overload in a conceptual modeling grammar is to create variations of the overloaded construct so that a one-to-one mapping exists between each variation and one of the reference ontological constructs. For instance, instances of the grammatical construct might be annotated, shaded, or colored in some way to indicate the particular ontological construct they represent.

15.3.1.4 Construct Excess

Recall, construct excess arises in a conceptual modeling grammar when a grammatical construct does not map to any construct in the reference ontology. In the presence of construct excess, TOE motivates a prediction that users of the grammar may become confused about the nature and purposes of the excess construct (at least from a conceptual modeling perspective). Moreover, stakeholders who have to interpret scripts containing instances of the excess construct may be confused about the real-world meaning to be ascribed to instances of the construct.

At first glance, the notion of construct excess might seem curious. After all, surely each construct in a conceptual modeling grammar must refer to *something*. As with construct deficit, overload, and redundancy, however, construct excess is determined relative to a particular ontological benchmark. In this light, a grammar may have construct excess according to one ontological benchmark but not another one. For any given benchmark, instances of excess may occur because the ontology is silent on its capacity to represent a particular type of phenomenon or because it expressly states a particular type of phenomenon does not exist in the real world.

Consider the case of optional attributes. Many conceptual modeling grammars have a construct that can be used to show whether an attribute of an entity is mandatory or optional. For instance, the closed (shaded) circle on the arc between the entity "PhD student" and the attribute "advisor's name" in Figure 15.8 indicates all PhD students must have an advisor. The open (unshaded) circle on the arc between the entity PhD student and the attribute "thesis title," however, indicates not all PhD students have finalized a thesis title.

When optional attributes are used in a conceptual model, the meaning intended is that only some instances of things (entities or objects) in a type or class of things possess the attribute. Conversely, some

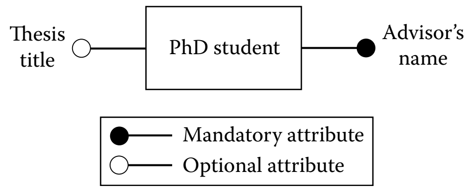

FIGURE 15.8 Entity with mandatory and optional attributes.

instances of things in the type or class possess a "negative" or "null" attribute—an attribute they do *not* have. For instance, in Figure 15.8, some instances of PhD student possess an attribute "does not have a thesis title."

In Bunge's theory of ontology, all properties of things must be mandatory—he brooks no notion of an optional or "negative" property (a property a thing does not possess). Specifically, he argues: "We certainly need negation to understand reality and argue about it or anything else, but external reality wears only positive traits" (Bunge, 1977, p. 60). We might conclude *logically* that something does not possess a property, but this conclusion does not mean the thing possesses the property of not possessing the property. The "negation" falls within the domain of logic and not the domain of ontology.

In the context of TOE, the optional attribute construct constitutes an example of construct excess. It is a grammatical construct that maps to no ontological construct. As a result, based on Bunge's theory of ontology, TOE motivates a prediction that users of scripts containing optional attributes will become confused when they have to interpret the scripts.

At first glance, it may not be clear why this outcome will occur. Problems become apparent, however, when having to reason about a thing that has two or more optional attributes. For instance, in Figure 15.9, two optional attributes of PhD students are "has a confirmed thesis title" and "has passed comprehensive examinations." Consider, now, the following question: Must all PhD students who have a confirmed thesis title also have passed their comprehensive examinations? The information contained in the conceptual model in Figure 15.9 does not allow us to answer this question. Figure 15.9's unclear semantics can be resolved, however, by using a subclass that has mandatory properties only. In this regard, Figure 15.10 shows PhD students who have a confirmed thesis title must also have passed their comprehensive examinations.

In three experiments, Bodart et al. (2001) investigated the impact of using optional attributes on users' understanding of conceptual models. Based on two theories of human memory—semantic network theory (Collins and Quillian, 1969) and spreading activation theory (Anderson and

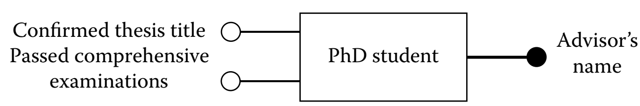

FIGURE 15.9 Conceptual model with unclear semantics.

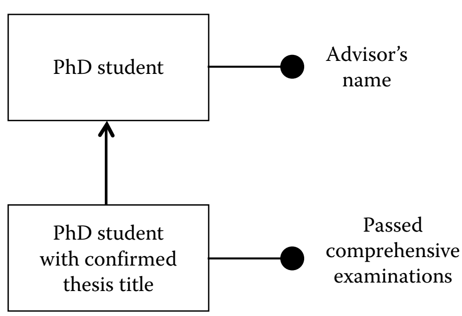

FIGURE 15.10 Conceptual model with clear semantics.

Pirolli, 1984)—Bodart et al. predicted optional attributes would assist users to undertake tasks where only a surface-level understanding of a conceptual model was needed. For instance, conceptual models with optional attributes might be satisfactory for senior management who are interested in obtaining only a broad understanding of a domain. Subclasses that have mandatory attributes only might clarify the semantics of a conceptual model, but this outcome is attained often at the cost of the model being more complex. Where users of conceptual models have to undertake tasks that require a deep-level understanding of a domain, however, Bodart et al. (2001) predicted use of subclasses with mandatory attributes only would be beneficial. For instance, database designers need to have a precise understanding of a domain's semantics when they design the normal-form relations to be used in a database. The experimental results obtained by Bodart et al. (2001) for the most part supported their predictions.

Gemino and Wand (2005) also investigated the impact of using optional versus mandatory attributes in conceptual models on users' understanding of a domain. Based on Mayer's (2001) cognitive theory of multimedia learning, they predicted users who were given a conceptual model that had subclasses with mandatory attributes only would have greater comprehension and understanding of the domain represented by the conceptual model than users who were given a conceptual model that had optional attributes. They found support for their predictions in the results obtained from a laboratory experiment they conducted.

Bowen et al. (2006) studied the impact of using optional versus mandatory attributes in conceptual models on users' performance in formulating SQL queries. On the one hand, they hypothesized use of mandatory attributes only in a conceptual model would assist users to formulate more accurate and more complete SQL queries because the domain's semantics were clearer. On the other hand, they hypothesized use of mandatory attributes only in a conceptual model would undermine users' query performance because they had to deal with a greater number of entities in the conceptual model (because more subclasses were present). In an experimental test of their hypotheses, overall they found users who received conceptual models with mandatory attributes only showed the highest levels of query performance. Nonetheless, detailed analyses of errors that their participants made revealed those who received conceptual models with mandatory attributes only made a greater number of certain types of errors—specifically, those where they had to use JOIN operations to assemble data from different relations (an outcome of the need for more subclasses in conceptual models with mandatory attributes only).

In their study of 12 process modeling grammars (see preceding text), Recker et al. (2009) were able to assess the level of construct excess in *seven* of the grammars they examined—namely, EPC, BPML, WSCI, ebXML, WS-BPEL, Petri nets, and BPMN. They measured construct excess by counting the number of grammatical constructs that did not map to any BWW construct and dividing this number by the total number of constructs in the grammar. The average measure of construct excess across the seven grammars was 22.09% (the range was 0%–42.90%). In other words, on average, approximately 22% of the constructs in the grammars did not represent an ontological construct.

In light of their analysis of construct excess, Recker et al. (2009) predicted users of the grammars they studied would encounter a number of difficulties. For instance, they concluded

- Some instances of construct excess arose because the grammars contained a mixture of conceptual, logical, and physical process modeling constructs. For instance, constructs such as "parameters" and "activity instance state" supported process implementation and execution rather than conceptual modeling of processes in a domain. As a result, the grammars were unnecessarily complex. Moreover, they confused the functions of analysis, design, implementation, and execution in process modeling.
- Some instances of construct excess arose because the grammars contained constructs to support the mechanics or "act" of modeling. For instance, constructs such as "off-page connector" or "text annotation" had the purpose of linking different parts of a model or providing supplementary descriptions for different components of the model. These constructs made the grammars more complex and would be better provided by tools developed to support use of the grammars.

In data obtained from their web-based survey of global BPMN users (see preceding text), Recker et al. (2011) found a negative association between the extent to which these users perceived BPMN had certain kinds of construct excess (e.g., "[t]he Basis Event symbol does not have any real-world meaning in a process model") and the extent to which they perceived BPMN was *easy to use*. They also found these users' perceptions of BPMN's ease of use declined as a function of the number of different types of construct excess the users had encountered.

Based on interview responses obtained from 19 business process modeling practitioners in six Australian organizations (see preceding text), however, Recker et al. (2010) found the impact of construct excess in BPMN on the practitioners' work was somewhat mixed. Certain excess constructs in BPMN were simply ignored by the practitioners, while others were deemed important to the "act of modeling" even though they have no real-world correspondence.

One way in which stakeholders might seek to cope with problems arising from construct excess in a grammar is to proscribe use of the excess constructs for conceptual modeling purposes. In some cases (e.g., optional attributes), the merits of the excess construct for any kind of purpose are debatable. In other cases (e.g., activity instance state), the excess construct might be useful for logical (design) and/or implementation modeling purposes. In these latter cases, proscribing their use during conceptual modeling will force modelers to clearly differentiate conceptual modeling activities from logical (design) and implementation modeling activities. The outcome should be that higher-quality work is done for each of the three kinds of modeling activities.

15.3.2 Conceptual Modeling Practice and the TMGS

Relative to TOE, only a small number of research studies have so far been conducted using TMGS. Moreover, most have used TMGS for analytical purposes (e.g., Green et al., 2007). Few studies have tested their analytical results empirically.

In an extensive study of stakeholders' use of a computer-aided software engineering tool, Green (1996) found the stakeholders acted strategically in the ways they chose from the set of modeling grammars provided in the tool to address problems caused by construct deficit in individual modeling grammars. First, they chose grammars to achieve MOC. Green found that, either consciously or subconsciously the stakeholders selected a set of grammars to try to ensure all constructs in the reference ontology he used (the BWW ontology) were covered by at least one of the grammars. Second, the stakeholders chose grammars to achieve MOO. Either consciously or unconsciously they selected a set of grammars to try to minimize construct redundancy. They seemed to recognize that having redundant grammatical constructs would cause them difficulties.

Green's (1996) research shows the MOC and MOO strategies are a good way for practitioners to deal with problems caused by construct deficit. Practitioners first need to select a reference ontology—one they feel is congruent with the ways they would like to model domains of interest to them. They then need to select a set of conceptual modeling grammars that appear capable of modeling these domains. Next, they need to analyze the ontological expressiveness of these grammars and examine alternative combinations of them to see how well they meet the MOC and MOO objectives. To achieve parsimony, they should choose the combination that includes the smallest number of grammars that achieves the MOC and MOO objectives.

15.4 Research Issues

The use of ontology as a theoretical underpinning for conceptual modeling phenomena is still a new field of research. Much work remains to be done before the merits of this approach as a means of improving our knowledge of conceptual modeling practice can be better understood. In this section, therefore, we briefly discuss some research opportunities that might be pursued.

15.4.1 Refining the TOE

The TOE (Wand and Weber, 1993) needs to be refined if its explanatory and predictive powers are to be improved. Several types of refinement might be undertaken:

- TOE motivates a prediction that construct deficit, redundancy, overload, and excess undermine stakeholders' ability to effectively and efficiently use conceptual modeling grammars and the scripts generated via these grammars. The ways in which stakeholders' performance will be undermined, however, are unclear. A taxonomy of stakeholders and the tasks they perform through engaging with conceptual modeling grammars and scripts needs to be articulated. The impact of grammar and scripts that lack ontological expressiveness on the different types of stakeholders and the different tasks they perform then needs to be enunciated. As noted earlier, for example, Bodart et al. (2001) predicted construct excess would be more problematical when readers had to engage in tasks that required them to have a deep rather than a shallow understanding of scripts. Depth of understanding required is just one way to differentiate tasks, however, and a more detailed taxonomy would assist future research.
- The nature of the associations between the four types of factors that undermine ontological expressiveness (construct deficit, redundancy, overload, and excess) and different outcome factors needs to be articulated more precisely. Currently, TOE simply indicates a negative effect on stakeholder performance will occur. A refined form of TOE would indicate the functional form of this effect. For instance, does the impact of increasing levels of construct overload have a negative exponential effect on stakeholder performance (i.e., increasing sharply and then leveling off)? Or, does the impact of increasing levels of construct overload follow a sigmoid shape (i.e., initially a slow increase, then a sharp increase, then a leveling off)? Stronger tests of theories are possible when the functional form of associations between their constructs are specified more precisely (Edwards and Berry, 2010; Weber, 2012).
- The relative strength of the effects of construct deficit, redundancy, overload, and excess on different types of stakeholders and different types of tasks has not been articulated. Moreover, the ways in which these factors interact is unknown. For instance, do higher levels of construct excess exacerbate the effects of construct overload because instances of excess constructs that seemingly have no real-world domain meaning compound the ambiguity surrounding instances of overloaded constructs in a script?

To some extent, refinements of TOE depend upon obtaining more empirical evidence from tests of TOE. For instance, evidence from such tests might indicate the relative weightings that should be assigned to different factors that undermine ontological expressiveness in terms of their impact on users of modeling grammars and the tasks in which they engage.

15.4.2 Refining the TMGS

Several types of refinement might be undertaken to the TMGS (Green, 1996):

- TMGS motivates a prediction that a higher level of ontological completeness among a set of conceptual modeling grammars is associated with a higher likelihood that the grammars will be used together for modeling purposes. The level of ontological completeness is measured in terms of the number of constructs in the reference ontology covered by constructs in the modeling grammars. For particular stakeholders and particular tasks, however, certain ontological constructs and thus certain grammatical constructs may be more important than others. A more refined measure of ontological completeness would therefore involve more than a simple count of the number of ontological constructs covered by the modeling grammars. Instead, it would incorporate a weighting of individual ontological constructs to reflect their relative importance for different stakeholders and different tasks.

- TMGS motivates a prediction that a higher level of ontological overlap among a set of conceptual modeling grammars will be associated with a lower likelihood that the grammars will be used together. The level of ontological overlap is measured in terms of the number of constructs in the reference ontology covered by more than one construct in the modeling grammars. As with the level of ontological completeness among a set of grammars, however, certain kinds of construct overlap may undermine stakeholder performance in different ways (perhaps as a function of the type of stakeholder and the type of task). A more refined measure of ontological overlap would take into account that certain kinds of overlap are more problematic than others.
- As TMGS currently stands, the likelihood of certain grammars being selected together for modeling purposes is not impacted by an interaction effect between the grammars' level of ontological completeness and level of ontological overlap. Such an interaction effect might be important, however, in the selection of grammars to use together. For instance, if ontological completeness can be achieved only with more ontological overlap, the benefits of ontological completeness may be diminished.

As with TOE, to some extent, refinements to TMGS depend on obtaining further empirical evidence from tests of TMGS. For instance, the results of such tests might provide insights into the relative weightings that should be assigned to different types of ontological completeness, and overlap in terms of their impact on the likelihood grammars will be used together for modeling purposes.

15.4.3 Testing Alternative Ontologies

Recall, TOE and TMGS are not tied to a particular theory of ontology. Nonetheless, as we have discussed earlier, many scholars have selected the BWW ontology as the reference ontology because it has been articulated rigorously and it contains constructs that seem especially relevant to the information technology field. Moreover, the BWW ontology has provided the basis for a number of predictions about conceptual modeling practice that have been supported empirically.

Nonetheless, some scholars believe that the BWW ontology provides a flawed foundation for evaluating conceptual modeling grammars and scripts (e.g., Guizzardi et al., 2006; Wyssusek, 2006). Unfortunately, while criticisms have been made of the BWW ontology, little work has been done to articulate alternative reference ontologies, adapt these ontologies to the information technology domain, evaluate the ontological expressiveness of conceptual modeling grammars using these ontologies, and empirically test the conclusions generated on the basis of such evaluations. Until such work is undertaken, the merits of alternative reference ontologies remain uncertain.

Comparative *analytic* evaluations of alternative ontologies (e.g., Chisholm, 1996) that could be used as a reference ontology for TOE or TMGS are likely to have merits. We believe, however, that better research outcomes will occur if predictions based upon the alternatives chosen are made and tested *empirically*. In particular, the most interesting predictions are likely to be those that *contradict* each other. By testing competing predictions empirically, the relative merits of alternative reference ontologies will become more apparent.

15.4.4 Improving the Design and Execution of Empirical Tests

Historically, for two reasons, undertaking valid and reliable empirical tests of conceptual modeling grammars and scripts has proved challenging. First, it is often difficult to mitigate threats to construct validity, internal validity, and external validity (Burton-Jones et al., 2009). Second, as discussed earlier, the theory that underpins the tests is imprecise and thus the ways the tests should be designed and the constructs measured are unclear.

To illustrate some of the difficulties encountered, consider Figures 15.5 and 15.6, which show two outcome constructs: user task effectiveness and efficiency and the likelihood of grammars being used

together. It is unlikely that these two constructs cover the full set of outcomes that might arise from having greater ontological expressiveness in a single grammar or combination of grammars. For instance, in a group setting, one outcome of interest might be the development of a shared understanding among users of a grammar (or set of grammars). Intuitively, clear conceptual models should help users reach a shared understanding. To the best of our knowledge, however, this outcome construct—shared understanding—has never been examined.

Even if we focus only on the outcome constructs shown in Figures 15.5 and 15.6, the best way to measure them is unclear. For instance, as a measure of task effectiveness and efficiency, researchers have used recall time, recall accuracy, comprehension scores, problem-solving scores, scores on fill-in-the-blank tests, cognitive breakdowns, and perceptual variables indicating users' ease of understanding conceptual models. The results have varied considerably depending on the particular measure chosen (Bodart et al., 2001; Burton-Jones and Meso, 2008; Gemino, 1998). More research is needed, therefore, to discern the best measures to use.

15.4.5 Action Research to Assist the Designers of Conceptual Modeling Grammars

There is little evidence to suggest the design of conceptual modeling grammars is informed by high-quality theory. Rather, the design of many current grammars seems to have been based on earlier grammars that were developed, perceptions about stakeholders' experiences with these grammars, the beliefs of influential individuals about appropriate features for a grammar, and the deliberations of and compromises reached by committees (Siau and Rossi, 2011).

Through action research (e.g., Davison et al., 2004), TOE could be used as the basis for designing new conceptual modeling grammars or refining and enhancing existing grammars. For new grammars, a set of constructs should be chosen so a one-to-one mapping exists between each construct and each construct in the reference ontology. For existing grammars, their constructs should be modified and/or enhanced to achieve a one-to-one mapping with ontological constructs. Moreover, for existing grammars, through the identification of construct excess (grammatical constructs for which no corresponding ontological construct exists), TOE may help clarify which, if any, grammatical constructs are focused on logical (design) modeling or implementation (physical) modeling. The grammatical constructs can then be partitioned and advice provided to users of the grammar about which constructs to employ for conceptual modeling and which constructs to employ for logical and implementation modeling. Such work hopefully would lead to better conceptual modeling practice as well as refinement and enhancement of TOE.

15.4.6 Action Research to Assist the Users of Conceptual Modeling Grammars

Through action research, TOE and TMGS could be used as the basis for assisting stakeholders to select conceptual modeling grammars best suited to their needs. Stakeholders first must choose a reference ontology. They then must identify which ontological constructs are important for their modeling needs (possibly all will be deemed necessary). Using TOE and the ontological constructs they have chosen, they can then evaluate the relative levels of ontological expressiveness possessed by the grammars they are considering. If the goal is to select only a single grammar for use, stakeholders will have to compare the costs of construct deficit, redundancy, overload, and excess among the grammars they are evaluating. If stakeholders are willing to engage with multiple grammars, a choice might be made by seeking to achieve the goals of MOC and MOO.

TOE might also be used as a basis for deciding how a conceptual modeling grammar (or grammars) should be used. For instance, in communicating the semantics of a domain to senior managers, some ontological constructs might not be deemed important. Senior managers might be interested in the

major things (objects) in a domain and how they are related, but they might not be interested in the intrinsic properties things possess or the nature of the state spaces or event spaces associated with things. An organization might put in place a set of standards and protocols that dictate what grammatical constructs will be used to generate scripts for particular stakeholders and particular tasks.

Where the conceptual modeling grammar used has construct redundancy, overload, or excess, an organization might also put in place a set of standards and protocols to mitigate any detrimental effects that might arise. For instance,

- In the case of construct redundancy, a standard might require that only one of the redundant grammatical constructs should ever be used to represent the reference ontological construct.
- In the case of construct overload, several versions of the grammatical construct might be created and somehow differentiated from each other so that a one–one mapping is achieved between the different versions of the grammatical construct and the reference ontological constructs.
- In the case of construct excess, a standard might require the excess constructs never be used to generate conceptual modeling scripts.

Via action research, stakeholder's experiences in using both TOE and TMGS can be documented and evaluated. Hopefully, stakeholder's performance in using conceptual modeling grammars and scripts can be improved and TOE and TMGS can be refined and enhanced.

One promising basis for future action research relates to the development of modeling rules or guidelines. The basic idea is to encapsulate the implications of theories such as TOE and TMGS in concrete rules or guidelines, whether for modeling domains in general (e.g., Evermann and Wand, 2005a) or modeling domains to support specific tasks (e.g., Bera et al., 2011). These rules or guidelines might then be incorporated in software to help analysts follow them more easily and accurately (Wand et al., 2008). Bera et al. (2011, p. 904) explain the logic underlying this stream of work:

> …the domain [should be] presented in a way that fits the task. This implies that aspects of the domain that are most relevant to the task…should be made salient in the representation. … This is where principles from philosophical ontology can provide guidance as to how the formal modeling grammar can be used to make the relevant domain aspects more salient in the script. We refer to this guidance…as "representational rules." In short, the approach we have followed is a method for creating representations that have ontologically informed fit for a given task.

Action researchers could test the benefit of these modeling rules and guidelines by first training people to use them or training them to use the software that implements them and then observing whether they improve modeling outcomes.

15.5 Summary

In this chapter, we have examined some ways in which the philosophical field of ontology has informed practice and research on conceptual modeling. Specifically, we have discussed how two theories that rely on ontological foundations have been used to predict, explain, and understand conceptual modeling phenomena. The first is the TOE, which allows the ontological completeness and clarity of conceptual modeling grammars to be evaluated. The second is the TMGS, which assists stakeholders to decide which combinations of conceptual modeling grammars they should use to undertake conceptual modeling work. We have examined the nature of these theories, some ways in which they have been used to generate recommendations for conceptual modeling practice, and some examples of research that has been undertaken to test predictions about conceptual modeling phenomena they have motivated.

Studying the ways in which ontological theories can be used to inform conceptual modeling practice and research is a relatively new field of endeavor. Much theoretical and empirical work remains

to be done. For instance, existing theories that rely on ontological theories, such as TOE and TMGS, need refinement and enhancement. Moreover, additional empirical research needs to be undertaken to evaluate these theories. Based on work done already, it is also clear that improved measures and procedures are needed to increase the validity and reliability of empirical work. Opportunities also exist to develop new, innovative ways in which ontological theories can be used to study conceptual modeling phenomena.

Glossary

Conceptual model: A representation, often graphical, of some features of a real-world domain; assists with the design, implementation, maintenance, and use of an information system.

Conceptual modeling grammar: Comprises a set of constructs to represent specific types of phenomena in a domain and a set of rules for combining the constructs to show how phenomena in the domain are related.

Conceptual modeling script: A string of instances of constructs in a conceptual modeling grammar that provides a representation of a specific domain.

Construct deficit: An attribute of a conceptual modeling grammar that arises when a construct in a theory of ontology cannot be represented by a construct in the conceptual modeling grammar.

Construct excess: An attribute of a conceptual modeling grammar that arises when a construct in the conceptual modeling grammar has no counterpart in a theory of ontology.

Construct overload: An attribute of a conceptual modeling grammar that arises when a construct in the conceptual modeling grammar is used to represent two or more constructs in a theory of ontology.

Construct redundancy: An attribute of a conceptual modeling grammar that arises when a construct in a theory of ontology can be represented by two or more constructs in the conceptual modeling grammar.

Grammatical construct: A component in a conceptual modeling grammar that is used to represent a specific type of phenomenon in the real world.

Ontology: A theory about the nature of and types of phenomena that exist in the real world.

Ontologically clear: An attribute of a conceptual modeling grammar that arises when the grammar has no instances of construct redundancy, overload, and excess.

Ontologically complete: An attribute of a conceptual modeling grammar that arises when the grammar has no instances of construct deficit.

Ontological construct: A component in an ontological theory that is used to represent a specific type of phenomenon in the real world.

Ontological coverage: The extent to which two or more conceptual modeling grammars have constructs that cover all constructs in a theory of ontology; analogous to ontological completeness for a single conceptual modeling grammar.

Ontologically expressive: An attribute of a conceptual modeling grammar that describes the extent to which the grammar represents the constructs in a theory of ontology in a complete and clear way.

Ontological overlap: The extent to which two or more conceptual modeling grammars have constructs that represent the same construct in a theory of ontology; analogous to construct redundancy for a single conceptual modeling grammar.

16.1 Introduction

Organizations have increasingly invested in technology and human resources to collect, store, and process vast quantities of data. Even so, they often find themselves stymied in their efforts to translate this data into meaningful insights that they can use to improve business processes, make smart decisions, and create strategic advantages. Issues surrounding the quality of data and information that cause these difficulties range in nature from the technical (e.g., integration of data from disparate sources) to the nontechnical (e.g., lack of a cohesive strategy across an organization ensuring the right stakeholders have the right information in the right format at the right place and time).

Although there has been no consensus about the distinction between data quality and information quality, there is a tendency to use *data quality* (DQ) to refer to technical issues and *information quality* (IQ) to refer to nontechnical issues. In this chapter, we do not make such distinction and use the term *data quality* to refer to the full range of issues. More importantly, we advocate interdisciplinary approaches to conducting research in this area. This interdisciplinary nature of research demands that we integrate and introduce research results, regardless of technical and nontechnical in terms of the

nature of the inquiry and focus of research. In fact, much of the research introduced here has a mixed focus, just as problems of data and information quality reveal themselves.

As a focused and established area of research, data and information quality began to attract the research community's attention in the late 1980s. To address data quality concerns, researchers at Massachusetts Institute of Technology (MIT) started investigating issues such as inter-database instance identification (Wang and Madnick 1989) and data source tagging (Wang and Madnick 1990). In 1992, the MIT's Total Data Quality Management (TDQM) program was formally launched to underscore data quality as a research area (Madnick and Wang 1992). The pioneering work at the MIT TDQM program and later MIT Information Quality (MITIQ) program laid a foundation for data quality research and attracted a growing number of researchers to conduct cutting-edge research in this emerging field. The substantial output of this research community has been a primary driver for the creation of related conferences, workshops, and a journal dedicated to the data and information quality, the *ACM Journal of Data and Information Quality (JDIQ)* (Madnick and Lee 2009a,b, 2010a,b).

This chapter provides an overview of the current landscape of data quality research and discusses key challenges in the field today. We do not attempt to provide a comprehensive review of all—or even most—prior work in the field. Instead, for each topic and method, we introduce representative works to illustrate the range of issues addressed and methods used in data quality research. The cited works also serve as pointers for interested researchers to other relevant sources in the literature.

The rest of the chapter is organized as follows. In Section 16.2, we briefly review some of the pioneering work in data quality. In Section 16.3, we present a framework for characterizing data quality research. In Section 16.4, we describe various research topics in data quality research and cite a sample of works to exemplify issues addressed. In Section 16.5, we review data quality research methods and show how they have been used to address a variety of data quality issues. Finally, in Section 16.6, we conclude the chapter with a brief discussion on the challenges that lie ahead in data quality research.

16.2 Evolution of Data Quality Research

Early data quality research focused on developing techniques for querying multiple data sources and building large data warehouses. The work of Wang and Madnick (1989) used a systematic approach to study related data quality concerns. Their research identified and addressed entity resolution issues that arose when integrating information from multiple sources with overlapping records. These researchers explored ways to determine whether separate records actually corresponded to the same entity. This issue has become known by terms such as *record linkage*, *record matching*, and more broadly, *data integration* and *information integration*.

Later, Wang and Madnick (1990) developed a *polygen* (*poly* for multiple and *gen* for source) model to consider the processing of data source tags in the query processor so it could answer data quality-related questions such as "Where is this data from?" and "Which intermediary data sources were used to arrive at this data?" Follow-up research included the development of a modeling method (known as the *quality entity–relationship* (ER) model) to systematically capture comprehensive data quality criteria as metadata at the conceptual database design phase (Wang et al. 1993; Storey and Wang 1998) and used an extended relational algebra to allow the query processor to process hierarchical data quality metadata (Wang et al. 1995a). This stream of research has led to impacts on modern database research and design such as data provenance and data lineage (Buneman et al. 2001) and other extensions to relational algebra for data security and data privacy management. More importantly, these early research efforts motivated researchers to embark on the systematic inquiry of the whole spectrum of data quality issues, which in turn led to the inauguration of the MIT TDQM program in the early 1990s and later the creation of the MITIQ.

16.2.1 TDQM Framework as the Foundation

Early research at the TDQM program developed the TDQM framework, which advocates continuous data quality improvement by following the cycles of *define*, *measure*, *analyze*, and *improve* (Madnick and Wang 1992). The framework extends and adapts the total quality management framework for quality improvement in the manufacturing domain (Deming 1982; Juran and Godfrey 1999) to the domain of data. A key insight was that although data is, in fact, a product (or by-product) *manufactured* by most organizations, it was not treated nor studied as such. Subsequent research developed theories, methods, and techniques for the four components of the TDQM framework, which we briefly describe next.

Define. A major breakthrough was to define data quality from the consumer's point of view in terms of *fitness for use* and to identify dimensions of data quality according to that definition via a systematic multistage survey study (Wang and Strong 1996). Prior to this research, data quality had been characterized by attributes identified via intuition and selected unsystematically by individual researchers. Key data quality dimensions were uncovered using a factor analysis on more than 100 data quality attributes identified systematically by the empirical survey study. These dimensions have been organized into four data quality categories: intrinsic, contextual, representational, and accessibility. Intrinsic DQ (e.g., accuracy and objectivity) denotes that data have quality in their own right. Contextual DQ (e.g., timeliness and completeness) emphasizes that data quality must be considered within the context of the task at hand. Both representational DQ (e.g., interpretability) and accessibility (e.g., access security) concern the role of systems and tools that enable and facilitate the interactions between users (including user applications) and data (Wang and Strong 1996).

Measure. A comprehensive data quality assessment instrument was developed for use in research as well as in practice to measure data quality in organizations (Lee et al. 2002). The instrument operationalizes each dimension into four to five measurable items, and appropriate functional forms are applied to these items to score each dimension (Pipino et al. 2002). The instrument can be adapted to specific organizational needs.

Analyze. This step interprets measurement results. Gap analysis techniques (Lee et al. 2002) reveal perceptual and experiential differences between data dimensions and data roles about the quality of data (Strong et al. 1997). The three major roles in and across most organizations are: data collectors, data custodians, and data consumers (Lee and Strong 2004). The knowledge held by different data roles reveals the different aspects and levels of knowledge held by different groups in and across organizations roles (Lee and Strong 2004). Analysis also identifies the dimensions that most need improvement and root causes of data quality problems.

Improve. In this step, actions are taken either to change data values directly or, often more suitably, to change processes that produce the data. The latter approach is more effective as discussed in Ballou et al. (1998) and Wang et al. (1998) where steps toward managing information as a product are provided. In addition, technologies mentioned earlier such as polygen and quality ER model (Storey and Wang 1998) can be applied as part of the continuous improvement process. When data quality software tools are embedded in the business processes, the strength and the limitation of the tools and the business processes need to be clarified (Lee et al. 2002). Experienced practitioners in organizations solve data quality problems by reflecting on and explicating knowledge about contexts embedded in, or missing from, data. These practitioners break old rules and revise actionable dominant logic embedded in work routines as a strategy for crafting rules in data quality problem solving (Lee 2004).

16.2.2 Establishment and Growth of the Field and Profession

In addition to developing and enriching the TDQM framework, the TDQM program and MITIQ program made significant efforts toward solidifying the field of data quality, broadening the impact of research, and promoting university–industry–government collaborations via publications, seminars,

training courses, and the annual International Conference on Information Quality (ICIQ) started in 1996. With the help of the TDQM and the MITIQ programs, the University of Arkansas at Little Rock has established the first-of-its-kind Master's and PhD data quality degree programs in the United States to meet the increasing demand for well-trained data quality professionals and to prepare students for advanced data quality research (Lee et al. 2007b).

Today, data quality research is pursued by an ever-widening community of researchers across the globe. In addition to ICIQ, other professional organizations have organized focused workshops on various areas within the field of data quality (e.g., SIGMOD Workshop on Information Quality in Information Systems, CAiSE Workshop on Information Quality, and SIGIQ Workshop on Information Quality). On the industry side of the data quality field, major software vendors have begun to implement data quality technologies in their product and service offerings. In government, data quality has become an important component in many e-government and enterprise architecture (EA) initiatives (OMB 2007). In the private sector, organizations have adopted variations on the TDQM methodology. An increasing number of companies have appointed a chief data officer (CDO) or senior executives with responsibilities similar to the CDO to oversee data production processes and manage data improvement initiatives (Lee et al. 2012). Some groups have started to use the title information strategists to signify that data quality has critical and compelling applicability for an organization's strategies.

In the meantime, data quality research faces new challenges that arise from ever-changing business environments, regulatory requirements, increasing varieties of data forms/media, and Internet technologies that fundamentally impact how information is generated, stored, manipulated, and consumed. Data quality research that started two decades ago has entered a new era where a growing number of researchers actively enhance the understanding of data quality problems and develop solutions to emerging data quality issues.

16.3 Framework for Characterizing Data Quality Research

An early framework for characterizing data quality research was presented in Wang et al. (1995b). It was adapted from ISO 9000 based on an analogy between physical products and data products. The framework consisted of seven elements that impact data quality: (1) management responsibilities, (2) operation and assurance costs, (3) research and development, (4) production, (5) distribution, (6) personnel management, and (7) legal function. Data quality research in 123 publications up to 1994 was analyzed using this framework. Although the framework was comprehensive, it lacked a set of intuitive terms for characterizing data quality research and thus was not easy to use. Furthermore, the seven elements do not provide sufficient granularity for characterization purposes.

To help structure our overview of the landscape of data quality research, we have developed a framework that is easier to use. We took a pragmatic approach to develop this framework based on two principles. First, the types of research topics continue to evolve. Instead of developing distinct or orthogonal categories, we selected and combined commonly known categories from various research communities to encourage multidisciplinary research methods. Second, research methods known and used by researchers have evolved over time and continue to be used in different disciplinary areas. Some methods overlap with others, but the methodological nomenclature offers a cue for researchers in corresponding research areas. Thus the framework has two dimensions, *topics* and *methods*, and is derived from a simple idea: Any data quality research project addresses certain issues (i.e., topics) using certain research methods. For each dimension, we have chosen a small set of terms (i.e., keywords) that have intuitive meanings and should encompass all possible characteristics along the dimension. These keywords are listed in Table 16.1, and their detailed explanations are provided in the next two sections. These topic and method keywords are also used to categorize papers submitted for publication in the *ACM JDIQ*.

For ease of use, we have chosen intuitive and commonly used keywords, such as *organizational change* and *data integration* for the topics dimension and *case study* and *econometrics* for the methods dimension. The methods and the topics are not necessarily orthogonal. We have grouped the topics into

TABLE 16.1 Topics and Methods of Data Quality Research

Topics	Methods
1. Data quality impact	1. Action research
1.1 Application area (e.g., CRM, KM, SCM, and ERP)	2. Artificial intelligence
1.2 Performance, cost/benefit, and operations	3. Case study
1.3 IT management	4. Data mining
1.4 Organization change and processes	5. Design science
1.5 Strategy and policy	6. Econometrics
2. Database-related technical solutions for data quality	7. Empirical
2.1 Data integration and data warehouse	8. Experimental
2.2 Enterprise architecture and conceptual modeling	9. Mathematical modeling
2.3 Entity resolution, record linkage, and corporate householding	10. Qualitative
2.4 Monitoring and cleansing	11. Quantitative
2.5 Lineage, provenance, and source tagging	12. Statistical analysis
2.6 Uncertainty (e.g., imprecise and fuzzy data)	13. System design and implementation
3. Data quality in the context of computer science and IT	14. Survey
3.1 Measurement and assessment	15. Theory and formal proofs
3.2 Information systems	
3.3 Networks	
3.4 Privacy	
3.5 Protocols and standards	
3.6 Security	
4. Data quality in curation	

four major categories. For the research methods, which are listed in alphabetical order, we have included terms with varying levels of specificity. For example, *econometrics* is more specific than *quantitative* method. This framework gives users the flexibility to choose a preferred level of specificity in characterization based on the tradition used in one's disciplinary background. When using the framework to characterize a particular piece of research, the researcher would choose one or more keywords from each dimension. For example, the paper "AIMQ: a methodology for information quality assessment" (Lee et al. 2002) addresses the *measurement* and *assessment* topic and uses a particular *qualitative* method (i.e., field study interviews and survey) along with a *quantitative* method (i.e., statistical analysis of data and analysis instrument).

We can also view the framework as a 2D matrix where each cell represents a topic–method combination. We can place a research paper in a particular cell according to the topic addressed and the method used. It is possible to place one paper in multiple cells if the paper addresses more than one issue and/or uses more than one method. A paper that uses a more specific method can also be placed in the cell that corresponds to a more general method. Obviously, some cells may be empty or sparsely populated, such as cells corresponding to certain combinations of technical topics (e.g., data integration) and social science methods (e.g., action research). Researchers are encouraged to consider employing more than one research method, including one or more quantitative methods with one or more qualitative methods.

In the next two sections, we use the framework to describe the landscape of data quality research. We also provide descriptions of keywords and illustrate their uses by citing relevant literature.

16.4 Research Topics

Data quality is an interdisciplinary field. Existing research results show that researchers are primarily operating in two major disciplines: management information systems and computer science (CS). We encourage researchers in other areas also to engage in data quality research, and we encourage

researchers in one field to borrow theoretical and methodological traditions from other disciplines as well. As a result of its interdisciplinary nature, data quality research covers a wide range of topics. In the subsequent sections, we provide a categorization scheme of data quality research topics. The scheme is broad enough to encompass topics addressed in existing research and those to be explored in future research. The scheme includes four major categories, each having a number of subcategories. A particular research activity can be categorized into multiple categories if it addresses multiple issues or multiple aspects of a single issue.

16.4.1 Data Quality Impact

Research in this area investigates impacts of data quality in organizations, develops methods to evaluate those impacts, and designs and tests mechanisms that maximize positive impacts and mitigate negative ones. There are five subcategories.

16.4.1.1 Application Area

Research in this category investigates data quality issues related to specific application areas of information systems such as customer relationship management (CRM), knowledge management, supply chain management, and enterprise resource management (ERP). For example, Mikkelsen and Aasly (2005) reported that patient records often contain inaccurate attribute values. These inaccuracies make it difficult to find specific patient records. In another study, Xu et al. (2002) developed a framework for identifying data quality issues in implementing ERP systems. Nyaga et al. (2011) explored drivers for information quality in contemporary inter-organizational supply chain relations. Heinrich et al. (2009) provided a procedure for developing metrics for quantifying the currency of data in the context of CRM.

16.4.1.2 Performance, Cost/Benefit, and Operations

Research in this area investigates the impact of data quality on the performance of organizational units (including individuals), evaluates the costs and benefits of data quality initiatives, and assesses the impact of data quality on operations and decision making. As suggested by Redman (1998), poor data quality can jeopardize the effectiveness of an organization's tactics and strategies. Poor data quality can be a factor leading to serious problems (Fisher and Kingma 2001). The impact of data quality and information about data quality on decision making has been investigated in several studies (Chengular-Smith et al. 1999; Raghunathan 1999; Fisher et al. 2003; Jung et al. 2005). Preliminary research has assessed the impact of data quality on firm performance (Sheng and Mykytyn 2002). Another study (Lee and Strong 2004) investigated whether a certain mode of knowledge, or *knowing-why*, affects work performance and whether knowledge held by different work roles matters for work performance. A recent study has shown evidence that the relationship between information quality and organizational outcomes is systematically measurable and the measurements of information quality can be used to predict organizational outcomes (Slone 2006). Still more research is needed to assess the impact of data quality on entities as diverse as individual firms and the national economy.

16.4.1.3 Information Technology Management

Research in this area investigates interactions between data quality and information technology (IT) management (e.g., IT investment, chief information officer (CIO) stewardship, and IT governance). The "fitness-for-use" view of data quality positions data quality initiatives as critical to an organization's use of IT in support of its operations and competitiveness. Organizations have begun to move from reactive to proactive ways of managing the quality of their data (Otto 2011). We expect to see more empirical studies that gauge their effectiveness and uncover other effects of proactive data quality management.

16.4.1.4 Organization Change and Processes

Ideally, data should be treated as a product, which is produced through a data manufacturing process. As suggested in prior research, data quality improvement often requires changes in processes and organizational behaviors. Research in this area investigates interactions between data quality and organizational processes and changes. For example, Lee et al. (2004) investigated data quality improvement initiatives at a large manufacturing firm, which iteratively adapted technical data integrity rules in response to changing business processes and requirements. A longitudinal study builds a model of data quality problem solving (Lee 2004). The study analyzes data quality activities portrayed by practitioners' reflection-in-action at five organizations via a 5 year action research study. The study finds that experienced practitioners solve data quality problems by reflecting on and explicating knowledge about contexts embedded in, or missing from, data. The study also specifies five critical data quality contexts: role, paradigm, time, goal, and place. Cao and Zhu (2013) investigated inevitable data quality problems resulting from the tight coupling effects and the complexity of ERP-enabled manufacturing systems in their case study.

16.4.1.5 Strategy and Policy

Research in this area investigates strategies and policies for managing and improving data quality at various organizational and institutional levels. For example, Kerr (2006) studied strategies and policies adopted by the healthcare sector in New Zealand. The study shows that the adoption of a data quality evaluation framework and a national data quality improvement strategy provides clear direction for a holistic way of viewing data quality across the sector and within organizations as they develop innovations through locally devised strategies and data quality improvement programs. Data quality strategies and policies at a firm level are laid out in Lee et al. (2006). Weber et al. (2009) studied a data governance model, including data quality roles, decision areas, and responsibilities.

16.4.2 Database-Related Technical Solutions for Data Quality

Research in this area develops database technologies for assessing, improving, and managing data quality. It also develops techniques for reasoning with data quality and for designing systems that can produce data of high quality. There are six subcategories.

16.4.2.1 Data Integration and Data Warehouse

Information systems within and between organizations are often highly distributed and heterogeneous. For analytical and decision-making purposes, there is a need to gather and integrate data from both internal and external sources (e.g., trading partners, data suppliers, and the Internet). Integration can be enabled via a flexible query answering system that accesses multiple sources on demand or via a data warehouse that pre-assembles data for known or anticipated uses. For example, Fan et al. (2001) provided ways to integrate numerical data. Data integration improves the usability of data by improving consistency, completeness, accessibility, and other dimensions of data quality. It is still an active research area after more than two decades of extensive study.

Goh et al. (1999) and Madnick and Zhu (2006) present a flexible query answering system, named COIN for *CO*ntext *IN*terchange, which employs knowledge representation, abductive reasoning coupled with constraint solving, and query optimization techniques. The system allows users to query data in multiple sources without worrying about most syntactic or semantic differences in those sources. In practice, many alleged "data quality" problems actually have been "data misinterpretation" problems. By understanding the contexts of both data sources and data consumers, *COIN* attempts to overcome data misinterpretation problems. It converts data, when necessary, to forms users prefer and know how to interpret.

Two other issues addressed by data integration research are entity resolution (sometimes known as record linkage or record deduplication, which is discussed later) and schema matching. Schema

matching research (Rahm and Bernstein 2001; Doan and Halevy 2005) develops techniques to automatically or semiautomatically match data schemas. The results can be used for a query answering system to rewrite queries using one schema to query against other matched schemas. The results can also be used to construct a global schema (Batini et al. 1986) for a data warehouse.

A data warehouse is often built via *extract, transform, load* (ETL) processes and provides tools to quickly interrogate data and obtain multidimensional views (e.g., sales by quarter, by product line, and by region). A framework for enhancing data quality in data warehouses is presented in Ballou and Tayi (1999). The data warehouse quality project (Jarkes et al. 1999) has produced a set of modeling tools to describe and manage ETL processes to improve data quality (Vassiliadis et al. 2001). In addition to various data cleansing tools designed specifically for ETL, a flexible query answering system such as COIN can be used as a transformation engine in ETL processes.

16.4.2.2 Enterprise Architecture and Conceptual Modeling

EA (Zachman 1987; Schekkerman 2004; OMB 2007) is a framework for understanding the structure of IT elements and how IT is related to business and management processes. EA allows an organization to align its information systems with its business objectives. This alignment is often accomplished by documenting, visualizing, and analyzing relationships between systems and organizational needs. EA methods have been widely used. For example, federal agencies in the United States are required to adopt a set of federal enterprise architecture methods in IT operations, planning, and budgeting (OMB 2007). Research in this area develops technologies to inventory, visualize, analyze, and optimize information systems and link their functionality to business needs.

Conceptual modeling is primarily used for database and system design. It is also useful for modeling EA. The ER model (Chen 1976) and its extensions are the most prevalent data modeling techniques. One important extension is to add data quality characteristics to an ER model. As illustrated in (Wang et al. 1993; Storey and Wang 1998), this extension captures data quality requirements as metadata at the cell level. Furthermore, the querying system can be extended to allow for efficient processing of data quality metadata (Wang et al. 1995a). Further research in this area aims to develop modeling extensions and query answering mechanisms to accommodate the need to manage data quality-related metadata such as quality metrics, privacy, security, and data lineage (Naumann 2002; Karvounarakis et al. 2010).

16.4.2.3 Entity Resolution, Record Linkage, and Corporate Householding

An entity, such as a person or an organization, often has different representations in different systems, or even in a single system. Entity resolution (Wang and Madnick 1989; Talburt et al. 2005), also known as record linkage (Winkler 2006) and object identification (Tejada et al. 2001), provides techniques for identifying data records pertaining to the same entity. These techniques are often used to improve completeness, resolve inconsistencies, and eliminate redundancies during data integration processes.

A corporate entity is often composed of multiple sub-entities that have complex structures and intricate relationships. There are often differing views about the structures and relationships of the sub-entities of a corporate entity. For example, the answer to "What was the total revenue of IBM in 2008?" depends on the purpose of the question (e.g., credit risk assessment or regulatory filing). The purpose would determine if revenues from subsidiaries, divisions, and joint ventures should be included or excluded. This phenomenon sometimes is known as the corporate household problem. In certain cases, it can be modeled as an aggregation heterogeneity problem (Madnick and Zhu 2006). More corporate household examples can be found in (Madnick et al. 2005). Actionable knowledge about organizations and their internal and external relationships is known as corporate household knowledge (Madnick et al. 2001). Corporate householding research develops techniques for capturing, analyzing, understanding, defining, managing, and effectively using corporate household knowledge. Preliminary results of using context mediation for corporate householding management can be found in (Madnick et al. 2004).

16.4.2.4 Monitoring and Cleansing

Certain data quality problems can be detected and corrected either online as data comes in or in batch processes performed periodically. Research in this area develops techniques for automating these tasks. For example, a technique for detecting duplicate records in large datasets is reported in (Hernandez and Stolfo 1998). The AJAX data cleansing framework has a declarative language for specifying data cleansing operations (Galahards et al. 2001). This declarative approach allows for separation of logical expression and physical implementation of data transformation needed for data cleansing tasks. The framework has been adapted for data cleansing needs in biological databases (Herbert et al. 2004).

16.4.2.5 Lineage, Provenance, and Source Tagging

Data lineage and data provenance information, such as knowledge about sources and processes used to derive data, is important when data consumers need to assess the quality of the data and make appropriate use of that data. Early research in this area (Wang and Madnick 1990) developed a data model that tags each data element with its source and provides a relational algebra for processing data source tags. A more general model was developed later (Buneman et al. 2001); it can be applied to relational databases as well as to hierarchical data such as XML. While much prior work focused on developing theories, an effort at Stanford University (Widom 2005) has developed a database management system to process data lineage information as well as uncertainties in data. A method of evaluating data believability using data provenance is developed in (Pratt and Madnick 2008).

16.4.2.6 Uncertainty

From a probabilistic viewpoint, there is a certain degree of uncertainty in each data element, or conversely, an attribute can probabilistically have multiple values. Numeric values also have a precision. Research in this area develops techniques for storing, processing, and reasoning with such data (Dalvi and Suciu 2007). For example, Benjelloun et al. (2006) present a novel extension to the relational model for joint processing of uncertainty and lineage information. While certain tasks require data with high precision and low uncertainty, other tasks can be performed with data that are less precise and more uncertain. Thus there is a need to effectively use data of differing levels of precision and uncertainty to meet a variety of application needs. Kaomea and Page (1997) present a system that dynamically selects different imagery data sources to produce information products tailored to different user constraints and preferences. In other cases, trade-offs need to be made between certainty or precision and other metrics of data quality. A mechanism of optimizing the accuracy–timeliness trade-off in information systems design is given in (Ballou and Pazer 1995).

16.4.3 Data Quality in the Context of Computer Science and Information Technology

Research in this area develops technologies and methods to manage, ensure, and enhance data quality. There are six subcategories.

16.4.3.1 Measurement and Assessment

To manage data quality, an organization first needs to evaluate the quality of data in existing systems and processes. Given the complexity of information systems and information product manufacturing processes, there are many challenges to accurate and cost-effective assessments of data quality. Research in this area develops techniques for systematic measurement of data quality within an organization or in a particular application context. The measurement can be done periodically or continuously. Lee et al. (2002) present a data quality assessment and improvement methodology that consists of a questionnaire to measure data quality and gap analysis techniques to interpret the data quality measures. Useful functional forms used for processing the questionnaire results are discussed in Pipino et al. (2002).

Data quality can also be assessed using other methods. For example, Pierce (2004) suggests the use of control matrices for data quality assessment. Data quality problems are listed in the columns of the matrix, quality checks and corrective processes form the rows, and each cell is used to document the effectiveness of the quality check in reducing the corresponding data quality problem. To improve the computation efficiency of data quality assessments in a relational database, Ballou et al. (2006) developed a sampling technique and a method of estimating the quality of query results based on a sample of the database. As more information is being generated on the web and through user contribution, numerous methods for measuring the quality of semi-structured and unstructured information have been developed (Gertz et al. 2004; Agichtein et al. 2008; Caro et al. 2008).

16.4.3.2 Information Systems

In the broad field of information systems, data quality research identifies data quality issues in organizations, investigates practices that enhance or deteriorate data quality, and develops techniques and solutions for data quality management in an organizational setting. For example, taking a *product* view of information (Wang et al. 1998), Wang and his colleagues (Wang 1998; Shankaranarayan et al. 2003) developed a modeling technique, called IPMap, to represent the manufacturing process of an information product (IP). Using a similar modeling technique, Ballou et al. (1998) illustrated how to model an information product manufacturing system and presented a method for determining quality attributes of information within the system. Lee et al. (2007a) developed a context-embedded IPMap to explicitly represent various contexts of information collection, storage, and use. In a 5 year longitudinal study of data quality activities in five organizations, Lee (2004) investigated how practitioners solved data quality problems by reflecting on and explicating knowledge about contexts embedded in, or missing from, data, and the contexts of data connected with otherwise separately managed data processes (i.e., collection, storage, and use).

16.4.3.3 Networks

There are a multitude of networks that connect various parts of a system and multiple systems. Networks can consist of physical communications networks, logic and semantic linkages between different systems, connections between systems and users, or even connections among users, such as social networks. Research into such networks can provide insights into how data are used and how the quality of data changes as data travel from node to node. These insights can be used to optimize network topology and develop tools for analyzing and managing networks. For example, O'Callaghan et al. (2002) proposed a single-pass algorithm for high-quality clustering of streaming data and provided the corresponding empirical evidence. Marco et al. (2003) investigated the transport capacity of a dense wireless sensor network and the compressibility of data.

16.4.3.4 Protocols and Standards

Data quality can be affected by protocols and standards. Research in this area develops protocols and standards to improve the quality of data exchanged among multiple organizations or within a single organization. Data standards improve data quality in dimensions such as consistency, interpretability, accuracy, etc. However, when data standards are too cumbersome, users may circumvent the standards and introduce data that deviate from those standards (Zhu and Wu 2011a). Thus research in this area also needs to study how protocols and standards impact data quality and how organizations can promote user compliance. In addition, the quality of the protocols or standards is also subject to quality evaluation. For example, Bovee et al. (2002) evaluated the quality of the eXtensible Business Reporting Language standard to see if its vocabulary is comprehensive enough to support the needs of financial reporting. Methods have also been developed to measure the quality of data standards (Zhu and Fu 2009; Zhu and Wu 2011b).

16.4.3.5 Privacy

Certain systems contain private information about individuals (e.g., customers, employees, and patients). Access to such information needs to be managed to ensure only authorized users view such data and only for authorized purposes. Privacy regulations in different jurisdictions impose different requirements about how private data should be handled. Violating the intended privacy of data would represent a failure of data quality. Although there have been commercial tools for creating privacy rules and performing online auditing to comply with regulations, there are still many challenges in developing expressive rules and efficient rule enforcement mechanisms. Recent research also addresses privacy preservation issues that arise when certain data must be disclosed without other private information being inferred from the disclosed data. Such research has focused on developing algorithms to manipulate the data to prevent downstream users from inferring information that is supposed to be private (Li and Sarkar 2006; Xiao and Tao 2006).

Privacy concerns engender multiple requirements. For example, one aspect of privacy, called *autonomy* is the right to be left alone. The "do not call" list in the United States is an example of legal protection for an autonomy requirement of privacy. As modes of communication with customers evolve, future research needs to develop effective solutions for describing the various privacy requirements and designing systems to meet these requirements. Further complicating privacy issues, some requirements such as those for data provenance can simultaneously increase quality while compromising privacy.

16.4.3.6 Security

Data security has received increasing attention. Research in this area develops solutions for secure information access, investigates factors that affect security, and develops metrics for assessing overall information security across and between organizations. A recent study (Ang et al. 2006) extends the definition of information security in three avenues: (1) *locale* (beyond the boundary of an enterprise to include partner organizations), (2) *role* (beyond the information custodians' view to include information consumers' and managers' views), and (3) *resource* (beyond technical dimensions to include managerial dimensions). This research attempts to develop an instrument for assessing information security based on this extended definition.

16.4.4 Data Quality in Curation

Digital curation is an emerging area of study originated in the fields of library and information science. It involves selecting, preserving, and managing digital information in ways that promote easy discovery and retrieval for both current and future uses of that information. Thus digital curation needs to consider current as well as future data quality issues. Consider the accessibility dimension of data quality: data preserved on 8 and 5 in. floppy disks have become nearly inaccessible because it is difficult to find a computer that is equipped with a compatible floppy drive. There are other technical and nontechnical issues that need to be considered. For example, implicit contextual information that is known today (and often taken for granted) and necessary to interpret data may become unknown to future generations requiring explicit capture now to ensure future interpretability of curated data.

Standards and policies can improve data curation processes and strategies. A collection of curation related standards can be found at http://www.dcc.ac.uk/diffuse/, a site maintained by the Digital Curation Centre in the United Kingdom.

In addition to database-related concerns, there are issues inherent in curation processes such as manually added annotations. Such manual practices provide challenges for data provenance requirements. Buneman et al. (2006) developed a technique to track provenance information as the user manually copies data from various sources into the curated database. The captured provenance information can be queried to trace the origins and processes involved in arriving at the curated data.

16.5 Research Methods

Just as there is a plethora of research topics, there is a wide range of research methods suitable for data quality research. We identify 15 high-level categories of research methods.

16.5.1 Action Research

Action research is an empirical and interpretive method used by researchers and practitioners who collaboratively improve the practices of an organization and advance the theory of a certain discipline. It differs from consultancy in its aim to contribute to theory as well as practice. It also differs from the case study method in its objective to intervene, not simply to observe (Baskerville and Wood-Harper 1996). An example of this research method can be found in Lee et al. (2004), which studied how a global manufacturing company improved data quality as it built a global data warehouse.

16.5.2 Artificial Intelligence

The field of artificial intelligence was established more than 50 years ago and has developed a set of methods that are useful for data quality research. For example, knowledge representation and automatic reasoning techniques can be used to enable semantic interoperability of heterogeneous systems. As demonstrated in Madnick and Zhu (2006), the use of such techniques can improve the interpretability and consistency dimensions of data quality. Agent technologies can be used to automate many tasks such as source selection, data conversion, predictive searches, and inputs that enhance system performance and user experience.

16.5.3 Case Study

The case study is an empirical method that uses a mix of quantitative and qualitative evidence to examine a phenomenon in its real-life context (Yin 2002). The in-depth inquiry of a single instance or event can lead to a deeper understanding of *why* and *how* that event happened. Useful hypotheses can be generated and tested using case studies (Flyvbjerg 2006). This method is widely used in data quality research. For example, Davidson et al. (2004) reported a longitudinal case study in a major hospital on how information product maps were developed and used to improve data quality.

16.5.4 Data Mining

Evolving out of machine learning of artificial intelligence and statistical learning of statistics, data mining is the science of extracting implicit, previously unknown, and potentially useful information from large datasets (Frawley et al. 1992). The data mining approach can be used to address several data quality issues. For example, data anomaly (e.g., outlier) detection algorithms can be used for data quality monitoring, data cleansing, and intrusion detection (Dasu and Johnson 2003; Petrovskiy 2003; Batini and Scannapieco 2006). Data mining has also been used in schema matching to find one-to-one matches (Doan et al. 2001) as well as complex matching relationships (He et al. 2004). While many data mining algorithms are robust, special treatment is sometimes necessary when mining data with certain known data quality issues (Zhu et al. 2007).

16.5.5 Design Science

There is an increasing need for better design of information systems as many organizations have experienced failed IT projects and the adverse effects of bad data. A systematic study of design science has been called for in the information systems community. With an artifact-centric view of design science,

Hevner et al. (2004) developed a framework and a set of guidelines for understanding, executing, and evaluating research in this emerging domain. As more artifacts such as quality ER (Wang et al. 1993; Storey and Wang 1998) and IPMap (Shankaranarayan et al. 2003) are created to address specific issues in data quality management, it is important that they are evaluated using appropriate frameworks, such as the one suggested in Hevner et al. (2004).

16.5.6 Econometrics

A field in economics, econometrics develops and uses statistical methods to study and elucidate economic principles. A comprehensive economic theory for data quality has not been developed, but there is growing awareness of the cost of poor quality data (Øvretveit 2000) and a large body of relevant literature in the economics of R&D (Dasgupta and Stiglitz 1980) and quality (De Vany and Saving 1983; Thatcher and Pingry 2004). As we continue to accumulate empirical data, there will be econometric studies to advance economic theory and our overall understanding of data quality practices in organizations.

16.5.7 Empirical

The empirical method is a general term for any research method that draws conclusions from observable evidence. Examples include the survey method (discussed later) and methods discussed earlier such as action research, case study, statistical analysis, and econometrics.

16.5.8 Experimental

Experiments can be performed to study the behavior of natural systems (e.g., physics), humans and organizations (e.g., experimental psychology), or artifacts (e.g., performance evaluation of different algorithms). For example, Jung et al. (2005) used human subject experiments to examine the effects of contextual data quality and task complexity on decision performance. Klein and Rossin (1999) studied the effect of error rate and magnitude of error on predictive accuracy. Li (2009) proposed a new approach for estimating and replacing missing categorical data. Applying the Bayesian method, the posterior probabilities of a missing attribute value belonging to a certain category are estimated. The results of this experimental study demonstrate the effectiveness of the proposed approach.

16.5.9 Mathematical Modeling

Mathematical models are often used to describe the behavior of systems. An example of this research method can be found in Ballou et al. (1998) where a mathematical model is used to describe how data quality dimensions such as timeliness and accuracy change within an information manufacturing system. System dynamics, a modeling technique originated from systems and control theory, has been used to model a variety of complex systems and processes such as software quality assurance and development (Abdel-Hamid 1988; Abdel-Hamid and Madnick 1990), which are closely related to data quality.

16.5.10 Qualitative

Qualitative research is a general term for a set of exploratory research methods used for understanding human behavior. Qualitative research methods suitable for data quality research include action research, case study, and ethnography (Myers 1997). Examples of data quality research that used action research and case study have been discussed earlier. Ethnography is a research method where the researcher is immersed in the environment of the subjects being studied to collect data via direct observations and interviews. The method was used in Kerr (2006), which studied data quality practices in the health sector in New Zealand.

16.5.11 Quantitative

Quantitative research is a general term for a set of methods used for analyzing quantifiable properties and their relationships for certain phenomena. Econometrics and mathematical modeling are examples of quantitative methods suitable for data quality research. See the discussions earlier for comments and examples of these method types.

16.5.12 Statistical Analysis

Statistical analysis of data is widely used in data quality research. For example, factor analysis was used in Wang and Strong (1996) to identify data quality dimensions from survey data. Furthermore, statistics is the mathematical foundation of other quantitative methods such as data mining and econometrics.

16.5.13 System Design and Implementation

This research method draws upon design methodology in software engineering, database design, data modeling, and system architecture to design systems that realize particular data quality solutions. Using this method, trade-offs in the feature space can be evaluated systematically to optimize selected objectives. Researchers often use this method to design and implement proof-of-concept systems. The COIN system (Goh et al. 1999) was developed using this research method.

16.5.14 Survey

Survey studies often use questionnaires as instrument to collect data from individuals or organizations to discover relationships and evaluate theories. For example, surveys were used in Wang and Strong (1996) to identify data quality dimensions and the groupings of those dimensions. A survey with subsequent statistical analysis was also used in Lee and Strong (2004) to understand the relationship between modes of knowledge held by different information roles and data quality performance and in Slone (2006) to uncover the relationship between data quality and organizational outcomes.

16.5.15 Theory and Formal Proofs

This method is widely used in theoretical CS research such as developing new logic formalism and proving properties of computational complexity. The method is useful in theoretical data quality research. For example, Shankaranarayan et al. (2003) applied graph theory to prove certain properties of IPMap. Fagin et al. (2005) formalized the data exchange problem and developed the computational complexity theory for query answering in data exchange contexts.

16.6 Challenges and Conclusion

Data quality research has made significant progress in the past two decades. Since the initial work performed at the TDQM program (see web.mit.edu/tdqm) and later the MITIQ program (see mitiq.mit.edu) at MIT, a growing number of researchers from CS, information systems, and other disciplines have formed a community that actively conducts data quality research. In this chapter, we introduced a framework for characterizing data quality research along the dimensions of topic and method. Using this framework, we provided an overview of the current landscape and literature of data quality research.

Looking ahead, we anticipate that data quality research will continue to grow and evolve. In addition to solving existing problems, the community will face new challenges arising from ever-changing technical and organizational environments. For example, most of the prior research has focused on the quality of structured data. In recent years, we have seen a growing amount of semi-structured and

unstructured data as well as the expansion of datasets to include image and voice. Research is needed to develop techniques for managing and improving the quality of data in these new forms. New ways of delivering information have also emerged. In addition to the traditional client–server architecture, a service-oriented architecture has been widely adopted as more information is now delivered over the Internet to traditional terminals as well as to mobile devices. As we evolve into a pervasive computing environment, user expectations and perceptions of data quality will also change. We feel that the "fitness for use" view of data quality has made some of the early findings extensible to certain issues in the new computing environment. Other issues are waiting to be addressed by future data quality research.

Much current research focuses on individuals and organizations. A broader perspective at a societal or group level can also be pursued. New research can also address issues that face inter-industry information sharing in this "big data" era, ushered in by increasingly diverse data consumers around the world in a social networking and networked environment. Researchers can collaborate across continents to uncover new insights into how data quality shapes global business performance and collaborative scientific endeavors, looking inward and outward. As seen in other areas, we envision an evolving set of topics and methods to address new sets of research questions by new generations of researchers and practitioners.

Knowledge Management

Susan Newell
Bentley University
University of Warwick

Marco Marabelli
Bentley University

Knowledge management (KM) refers to the multiple processes that support the creation and use of knowledge in an organization, or as March (1991) describes it, the exploration and exploitation of knowledge. KM is relevant to the information systems (IS) discipline, because information and communication technologies (ICT) are important tools involved in managing knowledge, especially given the increasingly distributed nature of organizational activity. However, despite the marketing of various ICT packages as "KM tools" by vendors, the IS discipline has recognized that ICT tools alone (i.e., the ICT artifact) are not sufficient. The combination of people and technology, in a particular context will influence how knowledge is produced and reproduced. This (re)production can be either purposive (e.g., when knowledge is integrated in order to develop a new method for dealing with customer enquiries or when knowledge is shared so that a new process in one geographical location can be reproduced in another location) or an emergent and unintended outcome of practice (e.g., when people start to use their e-mail to save important files for themselves rather than to communicate with other people). How the ICT, people, and context interrelationships are theorized will vary, of course, depending on the ontological and epistemological assumptions of the author (e.g., we will contrast an epistemology of possession and an epistemology of practice, Cook and Brown (1999), later in this chapter) but simplistic notions of ICT as the causal or determining factor in managing knowledge have long since been exploded, at least in the IS discipline. In other words, we now recognize that even though an organization might adopt ICT for some purpose (e.g., to improve knowledge sharing), simply introducing technology will not, on its own, lead to the desired change. Indeed, the introduction of ICT can sometimes have the opposite outcomes to those anticipated, for example, when the introduction of an intranet reduces knowledge sharing across organizational units rather than improving

knowledge sharing as intended (Newell et al., 2001). Thus, we do not agree with Spender (2006, p. 128) when he writes that: "IT or management information theorists and economists normally treat knowledge as separable from the people who generate and use it in their decision-making."

It is perhaps unfortunate that there is still a focus, even if only in practice and not our theorizing, on the ICT tools in KM. When things go wrong, the tools and the people who create the tools are then blamed, rather than recognizing the people–technology–context interactions that are actually at the root of any unsuccessful (as well as successful) initiative that is aimed to improve knowledge production and reproduction in an organizational context. This fallacy of blaming "the ICT" and information technology (IT) specialists for any KM initiative problem is captured nicely in the following joke that has done its rounds on the Internet:

> A man piloting a hot air balloon discovers he has wandered off course and is hopelessly lost. He descends to a lower altitude and locates a man down on the ground. He lowers the balloon further and shouts "Excuse me, can you tell me where I am?"
> The man below says: "Yes, you're in a hot air balloon, about 30 feet above this field."
> "You must work in Information Technology," says the balloonist.
> "Yes I do," replies the man. "And how did you know that?"
> "Well," says the balloonist, "what you told me is technically correct, but of no use to anyone."
> The man below says, "You must work in management."
> "I do," replies the balloonist, "how did you know?"
> "Well," says the man, "you don't know where you are, or where you're going, but you expect my immediate help. You're in the same position you were before we met, but now it's my fault!"

The skit nicely sums up how ICT (and those who work in the IT function) can become the scapegoat for KM initiatives. In this chapter, we will examine how a more sophisticated conceptualization of the interrelationships between people, technology, and context can help us to better understand how to create a working KM system for the production and reproduction of knowledge. We begin, though, with a discussion about "what is knowledge" because this is essential for our understanding of attempts to manage knowledge in an organization. We use production and reproduction of knowledge (rather than creation and use), because, as we will argue, knowledge is not transferred between individuals or collectives "ready-to-wear" or use directly. It is rather reproduced (or translated) in each new context of application, indeed, from a practice perspective, in each new moment of time.

Following the discussion on the nature of knowledge, the rest of the chapter is as follows: The next section provides an overview of knowledge (and KM) with respect to the epistemology of possession and the epistemology of practice; the following section (17.3) highlights how technology supports organizational memory (repository view), which is in line with the epistemology of possession. In contrast, Section 17.4 illustrates the "network view," which is rooted in the epistemology of practice. Section 17.5 provides an overview of KM systems (KMS), while Section 17.6 adopts the lens of absorptive capacity to highlight two contrasting aspects of knowledge: exploration and exploitation. The last section (17.7) draws some conclusions.

17.1 What Is Knowledge?

We watch detectives on TV piece together evidence, using a variety of tools, talking with colleagues, following up leads, interviewing suspects, and finally working out "who did it." The novice detective marvels at the demonstrated ability, having been unable himself/herself to make sense of all the various cues that point to the guilty suspect. We also watch doctors, ask others to do particular kinds of tests, conduct their own examination of a patient using various pieces of medical equipment, discuss the case with other specialists, and finally determine "what's wrong" and "what's the cure." Again, the trainee doctor can only stand and watch, unable to work out how all the different symptoms add up

to a particular diagnosis. We recognize these people as having (or not having) knowledge and acting (or not acting) knowledgeably. The main feature that distinguishes between the expert and the novice in these situations is their ability to differentiate within and between the patterns of complex information and data that they can draw upon in the particular context in which they are operating. As Tsoukas and Vladimirou (2001) put it, knowledge is “the individual ability to draw distinctions within a collective domain of action, based on appreciation of context or theory or both” (p. 979). The ability to discriminate and so draw meaning in a particular context, then, is the essence of knowledge. The next question is how do we gain knowledge?

Philosophers have long discussed and argued about this question. It has carried over into the social sciences generally today and into the area of KM very specifically. While there are multiple views, a helpful distinction in terms of the nature of knowledge and how knowledge is acquired is provided by Cook and Brown (1999). These authors distinguish between an epistemology of possession (that treats knowledge as something individuals and groups have or own based on prior experience but separable from that experience) and an epistemology of practice (that treats knowing as something people do that is context-dependent and socially situated). Essentially, this distinction differentiates between the idea that people “have knowledge” and that people “act knowledgeably.”

The possession perspective focuses on cognitions (mental processes) since it is the human mind that is viewed as the carrier or engine of knowledge. Knowledge is, thus, a personal property of an individual knower (or potentially also a collective, Spender (1996)), with mental processes being the key to conferring meaning from data and information, which exist “out there” (i.e., outside the head) in the world. These mental processes are the product of past experiences, perceptions, and understandings, which create a “frame of reference” that allows an individual to infer particular things (i.e., to make discriminations) from some data or information. So, an individual with prior training in physics can infer meaning from the equation—$e = mc^2$—that someone without this possessed knowledge will be unable to. This possessed knowledge includes both tacit and explicit knowledge (Polanyi, 1967). Explicit knowledge is that which can be written down or articulated in language or some other symbolic form. Tacit knowledge is knowledge that is impossible or certainly hard to write down and, even if written down, does not express the knowledge adequately. The example that is often used is knowledge to ride a bike. This includes both explicit knowledge (you must sit on the saddle and hold on to the handle bars, which might seem obvious to you but if you had never seen a bike before you would be unlikely to know that it was something you could sit on and peddle) and tacit knowledge (you must balance to stay upright). The knowledge of balance will always remain tacit—you can be told to shift weight if you are falling to one side, but what this “shifting weight” actually means cannot be explicitly shared, although once it is mastered, the individual will possess it as tacit knowledge. It is important to remember in Cook and Brown’s classification that both explicit and tacit knowledge are possessed knowledge (tacit knowledge is not the practice element), albeit the epistemology of practice is needed, in their view, to generate this possessed knowledge.

The epistemology of practice, then, sees knowledge, or better knowing, as intrinsic to localized social situations and practices where people perform or enact activities with a variety of others (both human and nonhuman) such that acting knowledgeably emerges from this practice and cannot be separated from this practice. Knowledge and practice are thus, immanent; knowledge is not something that stands outside of practice but is rather constantly (re)produced as people and their tools work together with certain consequences (which may be more or less intentional or purposive and which may demonstrate more or less “acting knowledgeably”). The collective, or community, within which practice is undertaken is characterized by a particular set of stories, norms, representations, tools, and symbols, which together produce the knowledge-related outcomes. These outcomes include the development of shared identities as well as shared beliefs, which underpin being a knowledgeable actor in any particular setting. Moreover, these outcomes are always emergent—never completely predictable.

Cook and Brown (1999) see these two epistemologies not as alternative or opposing views, but rather as complementary, with knowledge (possessed) being a tool of knowing. Possessed and practiced knowledge, thus, work together in what they describe as a “generative dance.” Gherardi (2006) refers to this as

the mutual constitution view of knowledge and she contrasts this with the containment and the radical practice views—all practice perspectives but differing slightly in their orientation.

The containment view focuses on how practice is developed within a specific community—of nurses, flute makers, photocopy technicians, tailors, radiologists, academics, etc. All the literature on communities of practice (Lave and Wenger, 1991) fits within this containment perspective and is focused on how newcomers learn "to be" nurses, flute makers, etc., through gradual participation in the situation of doing. A good example of such a containment perspective is demonstrated in the work of Julian Orr (1996) who examined the work of photocopy technicians and showed how learning to act knowledgeably occurred socially, often emerging through storytelling as well as through physical interactions with machines-in-context. In terms of storytelling, Orr observed that the technicians would meet up for coffee between site visits where they were repairing or maintaining copy machines. At these informal (and unofficial) meetings, they would tell "war stories" of machines they were or had been working on. These stories were crucial vehicles for the sharing of know-how that contributed to their skillful practice. Unfortunately, management saw the informal meetings rather differently—as unnecessary detours from their next scheduled visit and sought to outlaw the meetings. Ironically, as Orr relates, in doing so they reduced the ability of the technicians to learn their skills. In terms of interactions with machines-in-context, Orr points out that technicians needed to observe the copy machine in-context because its situated use would provide vital cues as to what might be the problem. Such cues could never be part of the training manual because there were so many aspects of the context that might be relevant. Learning to act knowledgeably, then, is socially situated within a particular community of practice.

The radical view, on the other hand, broadens this perspective, focusing on the interconnectedness of practices within any social setting or as Nicolini (2011) refers to it, in a "site of knowing." From this perspective, it is not individual cognitions that are important but the discursive practices, artifacts, and spaces that form a nexus for knowledgeable action in a particular context. For example, in a hospital, there may be a variety of communities of practice (nurses, oncologists, radiologists, and even patients with a particular disease), and to understand practice in this setting, it is important to look at the interrelationships between these communities as well as the relationships between people and objects and spaces. The knowing of the oncologist is intimately tied up with the tools that she uses and the relationships she has with a variety of other healthcare professionals (and the patient) in this setting. Without these relationships, she could not act knowledgeably. Within this context, or site of knowing, people and objects do not "carry knowledge" but instead are mediators that are actively translated (Latour, 2005) either "by contact" or "at distance" (Nicolini, 2011). Given this process of translation, practice (and so knowing) is always emergent—"pursing the same thing, necessarily implies doing something different" (Nicolini, 2007, p. 893–894). Translation captures the idea that knowledge is (re)produced rather than transferred, so that certain elements will be foregrounded or take on different meaning depending on the context and the mix of actors (human and nonhuman) that are present. Knowing is in these relationships, rather than in the heads of the individuals involved.

While the details of the differences between these practice views can be important, the key point that we wish to make in this chapter is that it is crucial to see knowledge as something that does not simply reside in individuals' minds, but rather recognize how knowing is a practical accomplishment. A chef cannot become a master chef simply by reading about cooking or even by practicing in isolation; rather she becomes a master through working in a particular kitchen where certain norms and values, together with particular culinary tools and ingredients, produce and re-produce her ability to act knowledgeably, as an emergent accomplishment of the social setting.

Moreover, the distinctions between knowledge as possession and practice and the different variants of the practice perspective are important because they influence how one views the interrelationships between people, technology, and context. We will next discuss two different images of the role of technology and the associated views of people and contexts in relation to KM: the repository view (that we link to the possession view of knowledge and the socio-technical school in IS) and the network view (that we link to the practice perspective of knowledge and the sociomateriality school in IS). The repository versus

network views have been previously discussed (Alavi and Tiwana, 2002). More recently, McAfee (2006) has distinguished between the platform and channel views of KM, which is very similar. These authors, however, make these distinctions based on developments in IT (from Web 1.0 to Web 2.0 and beyond), while we think it is important to see these different views of KM not as a product simply of technological advancement, but in terms of the epistemological perspective on knowledge and the ontological assumptions about the people–technology relationships that underpins their use.

17.2 Repository View

The repository view is probably the best established view of KM and is linked to the knowledge as possession perspective discussed earlier. From this perspective, individuals own knowledge, but they can also transfer knowledge to others, just as if I own a book I can give it to someone else, if I so choose. The idea behind the repository then is that individuals are encouraged to make explicit their knowledge (typically through a written document but this could also be through other media, like a film). This knowledge is then stored in a repository of some kind (typically a database using a document management system of some kind that can be accessed through an intranet that includes a search engine). Others can then search the repository when they need certain knowledge that they lack, and once they find what they are looking for, they can then apply this knowledge in their own context. It is a supply and demand model—those who have knowledge provide it for those who need it.

The repository view does not assume that putting in place a searchable database will alone be sufficient to improve knowledge sharing in an organization. In other words, it is recognized that the repositories on their own will not improve KM across an organization, in the absence of attention to the social aspects of organizing (Connelly et al., 2012). We can describe this as a socio-technical perspective (Kling and Courtright, 2006) on KM (Davenport and Prusak, 1998). A socio-technical perspective recognizes how the social and the technical influence each other so that what may seem like a perfect technical solution may not operate as such, because it undermines some aspect of the social, like motivation. The technical and the social are seen as having separate ontological status but are recognized to influence each other. It is, therefore, important from a socio-technical perspective to ensure that the social and the technical are aligned in relation to the goals that one is trying to pursue. For example, implementing a lessons learned database for project managers to store their experiences from which others can learn may not be effective if project managers are very time-pressured and/or not recognized for adding to the lessons learned database. It is also not very helpful if project managers are encouraged to share their knowledge if, at the same time, they are not also encouraged to look for and reuse knowledge from others (the demand side must be addressed as well as the supply side, an issue which has often been ignored in KM initiatives; Newell and Edelman (2008)). A number of factors, therefore, are recognized as being crucial to the success of such an initiative. We discuss some of those issues next.

17.2.1 Sticky Knowledge

While the repository view assumes that knowledge can be transferred from place to place, it also recognizes that some knowledge, especially tacit knowledge, can be more difficult to transfer because as Szulanski (1996) notes, knowledge can be "sticky." Nonaka (1994) suggests that this problem can be overcome by converting tacit knowledge to explicit knowledge. However, as already hinted at, this misunderstands the essential nature of tacit knowledge, which, as Polanyi (1961) indicates, will always remain tacit. Tsoukas (1996) summarizes this nicely when he refers to tacit and explicit knowledge as "mutually constituted," meaning that in any knowledgeable act, there will always be both tacit and explicit knowledge at work.

Sticky knowledge that is tacit may, then, simply not be transferable through a repository, but this still leaves a lot, from the possession perspective that can be shared. Stickiness, however, resides not just in the tacitness of knowledge but also in the fact that people have to be persuaded to both share their knowledge at the supply end and then use knowledge from elsewhere at the demand end. This is

where the "people aspect" of KM is often discussed. Incentives may be necessary to encourage people to share their knowledge, because knowledge is often a source of power in an organization (Bartol and Srivastava, 2002). Knowledge hoarding can, thus, be a major barrier to the success of a KM repository initiative (Lam and Chua, 2005). This means that incentives may be needed either to discourage hoarding or because it is time-consuming to "make one's knowledge available to others" (Alavi et al., 2006). Incentives may be financial but they can also be symbolic, as when knowledge workers share knowledge to increase their professional reputation (McLure-Wasko and Faraj, 2005).

Moreover, the possession perspective would also recognize that an individual's mind is not open to receive any kind of new knowledge—there is a path dependency to knowledge accumulation (see section on absorptive capacity). So there will be barriers to knowledge sharing, for example, across departments where different syntax is used, or where meanings are different (Carlile, 2004) (see following section on knowledge boundaries).

17.2.2 Leaky Knowledge

While from the repository view the stickiness of knowledge has to be overcome, it is also the case that because knowledge can be so readily transferred, it also has to be protected since it is the main source of sustainable advantage (Trkman and Desouza, 2012), as per the resource-based (Barney, 1991) or knowledge-based view of the firm (Grant, 1996). Technical solutions to this problem are addressed to securing databases and other ICT from unwanted predators. In fact, knowledge leaks associated with security breaches are not infrequent (Desouza and Vanapalli, 2005); for instance, Fitzgerald (2003) documents a number of cases of loss of intellectual property and sensitive data due to weak security measures. However, it is also recognized that a focus on the social is important. This can be in the form of contractual obligations, for example, with stipulating that an individual leaving an organization is not allowed to join a competitor within a certain amount of time, or it can take the form of training to encourage employees to have secure passwords (not sticky-taped to their computer) or to know what information is propriety and so should not be shared. Leaky knowledge is, in effect, the opposite of absorptive capacity (Cohen and Levinthal, 1990; Zahra and George, 2002) discussed below. Absorptive capacity is about building the capacity to recognize, process, and use external knowledge, while in this section, we have been discussing the importance of protecting organizational knowledge from external parties.

17.2.3 Organizational Culture

Given these issues of both sticky and leaky knowledge, scholars have identified organizational culture as key to effective KM practice. People need to be encouraged to share their knowledge and reuse others' knowledge through developing a culture or climate that encourages such activity (Alavi et al., 2006), or the culture needs to prevent such sharing where this is important. Culture refers to the basic assumptions and values that exist within an organization (Schein, 1992). There can be multiple cultures across an organization (Meyerson and Martin, 1987), but the key is that culture has been shown to be either an enabler (Alavi et al., 2006) or barrier (Connelly et al., 2012) to KM success. The cultivation of a culture that supports knowledge sharing has thus been described as an essential facilitator of the ability to exploit a KM repository (Donate and Guadamillas, 2010). Hackett (2000) describes this as a knowledge-sharing culture, which should include a shared vision, value-based leadership at all levels, openness and continuous communication, and rewards and recognition.

17.3 Network View

The network view has been linked to the emergence of social networking sites that encourage social exchanges in a much more dynamic and personalized way than repositories can. Social media are not simply platforms that individuals can communicate from (to one or many) but instead provide tools

for ongoing dynamic exchanges using multiple channels, including video, text, chat, and discussion forums. The network view is linked to the communities of practice perspective on knowledge sharing (Wenger et al., 2002) and to the practice perspective of knowledge more generally (Gherardi, 2006). Since knowing is an emergent outcome that is negotiated through social and material interactions, repositories that contain knowledge that is divorced from context are seen to be less helpful. However, ICT that can promote dialogue and shared experiences (albeit virtual) can play a role in the social learning process that underpins becoming a knowledgeable actor. Moreover, ICT is not just a pipe through which knowledge flows, rather ICT is seen to be part of the very practice itself, scaffolding that practice along with a host of other actors (material and human). We can describe this as a sociomaterial perspective (Feldman and Orlikowski, 2011).

From a sociomaterial perspective, it is not simply that the social and the technical are inter related, rather they are seen as "constitutively entangled in everyday life" (Orlikowski, 2007, p. 1437). As Pickering (1993) suggests, subjects and objects are mangled in the flow of practice, which can be seen as a series of resistances and subsequent accommodations in an ongoing flow of activity that is directed toward some goal (in the case he describes, the creation of a bubble chamber by a physicist). In the ongoing flow of practice, it is not possible or useful to distinguish between the social and the technical/material because they are entangled together in a form of "absorbed coping" (Dreyfus, 1995). Only when something breaks down, are we able to separate (artificially) the social and the material elements of the practice (Sandberg and Tsoukas, 2011).

From the practice perspective, ICT is a potential mediator, which will provide access to information that will be translated-in-context. For example, Nicolini (2011), examining telemonitoring in a hospital, describes how the ICT, infrastructures, programs, and interfaces that allow the doctors to collect information from a patient's home are all mediators of knowledge that is translated in different settings. For instance, Nicolini (2011) quotes a dialogue (phone call) between a patient (at home) and a nurse (in the hospital). The nurse first gathers a lot of information from the patient (i.e., the patient was sick the previous night, his daily pressure reading is fine, and he made a decision to stop taking a drug). Then the nurse needs to reach the doctor (in the example, a cardiologist), refer everything to him/her, and make sure that the doctor listens carefully to the whole conversation and makes the right decisions that will be then be reported to the patient (as Nicolini highlights, from the nurses perspective, "often doctors listen to you only briefly and support your decisions"—p. 7). In this example, the nurse acts as a mediator "at distance" that *translates* knowledge across contexts.

Given that, from this perspective, the social and the technical are seen as inseparable, it would not be sensible to think about ICT independent of its use in practice. Nevertheless, there are a number of important points to recognize from this perspective, which we discuss next.

17.3.1 Emergent (Unintended) Use

The material (including ICT) may scaffold the social (Orlikowski, 2007), but the scaffold is not fixed in design but rather unfolds through practice. So, the video conferencing facility that was designed to support virtual teamwork may be used by those involved in the project to watch movies together, rather than to hold joint team working sessions. In other words, from the practice perspective, there is always some emergence that may not be predicted but which managers need to be aware of if they hope to promote knowledgeable work. In saying this, we are not suggesting that managers should be trying to constrain this emergence—a distributed team using their video connection to watch films together (rather than, or at least as well as, to conference call) may actually promote strong team bonds that can facilitate project work (as with Orr's photocopy technicians taking time out to meet and chat between customer visits). Managers rather should be aware of why emergence happens and work with the users to create technical scaffolds that can support the work that they are doing, in ways that suit the particular context, recognizing that this may differ across time and space.

17.3.2 Role of Boundaries

The role of boundaries in managing knowledge is crucial for both the possession and the practice perspectives; boundaries exist between groups of any kind that are needing to share knowledge. Carlile (2004) distinguishes between syntactic, semantic, and pragmatic boundaries that increase in importance as the novelty of the collaboration increases, making knowledge sharing increasingly difficult:

Syntactic boundaries: When novelty is low and there are few differences between those sharing knowledge because they have worked on similar problems before, the main boundary is a syntactic one. Developing and maintaining a common lexicon can resolve this boundary problem. Once a common lexicon is in place, knowledge can be *transferred* relatively unproblematically (Carlile, 2004, p. 558).

Semantic boundaries: As novelty increases, differences between the collaborating groups become greater since they are working on new problems so that there are likely to be more ambiguities because there will be different meaning for the same word or convention, for example, about what to call something. Different workers might use conventions that are not clear to those outside a "circle," leading to different interpretations. In these situations, ambiguous terms and expressions (semantics) need to be *translated* to ensure consistent use of words and conventions.

Pragmatic boundaries: In situations where novelty is high, differences between collaborating groups are likely to cause the most problems for knowledge sharing. In these situations, it is not simply that different groups have different meaning systems, but that there are political issues associated with whose knowledge is to be most highly valued. Thus, we are "invested" in our knowledge, and if a change threatens our knowledge, we will resist it. For example, in healthcare, a new medical breakthrough may potentially move the treatment of a particular disease like cancer from surgeons (who cut out the cancerous cells) to radiologists (who kill the cells using radioactive treatments), and in this situation, we might expect the surgeons to resist the change (Swan and Scarbrough, 2005). In these situations, knowledge needs to be *transformed* through negotiations that may eventually change the frame of reference, dominant values, and the practices of the participating parties.

Linking this work on boundaries to the different perspectives on knowledge, from the possession perspective, the major challenges related to sticky knowledge are addressed by overcoming syntactic and semantic boundaries. However, from the practice perspective, a more formidable challenge is to overcome pragmatic boundaries that arise because we are invested in our practices (Carlile, 2004). Thus, while Nonaka (1994) defines knowledge as "justified true belief" what is justified depends on ones' practice history. In this sense, it is the boundaries between communities that create problems for knowledge sharing with community members "blinded" by their particular worldview and taken-for-granted sociomaterial practices. Since most action in organizations occurs in the context of multiple communities "tied together by interconnected practices" (Gherardi and Nicolini, 2002), the socially situated and contextually based nature of knowing poses as many problems as opportunities. Recognizing pragmatic boundaries between diverse epistemic communities (Knorr-Cetina, 1999) indicates the importance of considering the role of boundary objects (Star, 1989) and mediators (Latour, 2005) for helping the translation (or transformation in Carlile's terms) of knowledge across communities and contexts.

17.4 Technology for Support of KM Processes

While earlier we have differentiated between the repository and network views of KM and suggested that these are the product of different epistemological and ontological assumptions, in reality, most organizations combine the repository and network perspectives in developing their KMS. This is consistent with our mutual constitution view that recognizes both possessed knowledge and practice-based knowing. A variety of technical systems are thus introduced, together with social systems that can support the use of these technical systems. Quaddus and Xu (2005), for example, identified a number KMS, which are reported in Table 17.1 (the % in the table indicates the popularity of the different technologies).

TABLE 17.1 Technology-Based Knowledge Management Systems

E-mail (92%)	Video conferencing (43%)	Electronic bulletin boards (29%)	Best practice database (22%)	Extranet (17%)
Internet (90%)	Online discussion systems (40%)	Electronic meeting systems (26%)	Corporate yellow pages (22%)	Issue management systems (16%)
Databases (86%)	Workflow systems (39%)	Learning tools (25%)	Online analytical processing systems (21%)	Knowledge directories (15%)
Intranet (80%)	Data warehousing/ mining (37%)	People information archive (23%)	Knowledge repositories (21%)	Expert systems (8%)
Document management systems (60%)	Search and retrieval tools (36%)	Decision support systems (23%)	Knowledge portals (19%)	Artificial intelligence (5%)
Customer management systems (48%)	Executive information systems (34%)	Groupware (22%)	Lessons-learnt databases (18%)	

TABLE 17.2 Knowledge Management System and Knowledge Processes

Knowledge Process	Knowledge Creation	Knowledge Storage	Knowledge Transfer	Knowledge Application
KMS	–E-learning systems	–Knowledge repositories (data warehousing and data mining)	–Communication support systems (e-mail)	–Expert systems
	–Collaboration support systems		–Enterprise information portals (intranets/ internets)	–Decision support systems

Alavi and Tiwana (2002) categorize these different KMS in terms of the knowledge processes that they aim to enhance (knowledge creation, storage, transfer, and application) as depicted in Table 17.2.

This is helpful in the sense that it recognizes that different types of ICT will be more or less useful for different knowledge processes. At the same time, the Quaddus and Xu (2005) study demonstrates that it is the storage and transfer technologies (based on the repository view) that have been most popular in terms of the types of KMS that are used in practice. However, unfortunately this was a 2005 published paper and may not reflect the current state of play.

17.5 Knowledge Exploration and Exploitation

Most of the discussion so far has considered knowledge at the individual or local level—in particular, sites of knowing. However, we are also interested in looking at KM from an organizational perspective. On the one hand, organizational knowledge can be described as "more than the sum of the parts" (Simon, 1962); on the other hand, "organizations know more than they can tell" (Polanyi, 1967). To some extent, these two sayings reflect the possession and the practice perspectives, respectively, and so from a mutual constitution perspective, both are, paradoxically, insightful even though they seem to be opposite ideas. Moreover, from the perspective of this section of the chapter, the issue of organizations knowing more than they can tell relates to the problems surrounding exploitation, while the issue of organizational knowledge being more than the sum of the individual parts relates to the opportunities for exploration.

It is widely argued that organizational knowledge is a key asset for any organization and can lead to success (Grant, 1996). It is also suggested that a balance between knowledge exploration and knowledge

exploitation is positively associated with performance (Cohen and Levinthal, 1990; Levinthal and March, 1993). Among others, March (1991) indicates that achieving a balance between exploitation and exploration will affect an organization's survival and prosperity. In this section, we aim to deepen the issues associated with organizational knowledge, knowledge exploration, and knowledge exploitation. In so doing, we will apply the lens of absorptive capacity (Cohen and Levinthal, 1990), that is, the capability to capture external knowledge and transform it into organizational assets for innovation. In particular, we will focus on Zahra and George's (2002) reconceptualization of the construct. In their paper, they highlight that knowledge should be "explored" (potential absorptive capacity) and then "exploited" (realized absorptive capacity), and they also provide a process view of knowledge absorption that fits with the view of managing knowledge taken in this chapter.

17.5.1 Absorptive Capacity (a la Zahra and George)

Absorptive capacity was originally defined by Cohen and Levinthal (1990) as "the ability of a firm to recognize the value of new, external information, assimilate it, and apply it to commercial ends" (p. 128). Cohen and Levinthal (1990) also suggest that organizational absorptive capacity (1) builds on prior investments in building absorptive capacity in individuals; (2) develops cumulatively and tends to be path-dependent (i.e., what has been learnt in the past sets limits on what can be learnt in the future); and (3) depends on the organization's ability to share knowledge internally. Thus, since individual learning is cumulative, learning performance is greater when the object of learning (the new knowledge to be identified, assimilated, and applied) is related to what individuals already know. In sum, absorptive capacity is a mix of capabilities that allow individuals and organizations to capture external knowledge, process it, and apply it to innovation and therefore to organizational performance.

Zahra and George (2002) revised the absorptive capacity construct and highlighted that it has two main states, potential and realized: "potential capacity comprises knowledge acquisition and assimilation capabilities, and realized capacity centers on knowledge transformation and exploitation" (p. 185). This suggests that potential absorptive capacity captures processes of (external) knowledge exploration; that is, organizational actors scan the external environment with the aim to identify knowledge that, potentially, can be processed and used within the organization. However, potential absorptive capacity "does not guarantee the exploitation of this knowledge" (Zahra and George, 2002, p. 190). Realized absorptive capacity reflects the firm's capability to elaborate and exploit the knowledge that has been identified. Therefore, knowledge exploration and knowledge exploitation are complementary (March, 1991). Moreover (as discussed in the next sections), processes and mechanisms that support potential absorptive capacity incorporate characteristics of the epistemology of possession while processes and mechanisms that support realized absorptive capacity incorporate characteristics of the epistemology of practice. This twofold lens of analysis of absorptive capacity (possession vs. practice perspective) and the assumption that potential and realized absorptive capacity are complementary follow the mutual constitution view of knowledge that was introduced in the first part of this chapter. The next paragraphs discuss this in more detail.

17.5.2 Potential Absorptive Capacity and the Epistemology of Possession

Potential absorptive capacity includes two main capabilities: knowledge acquisition and knowledge assimilation (Zahra and George, 2002).

Knowledge acquisition is the firm's capability to identify and acquire only the external knowledge that is relevant for its business; that is, not all external knowledge should be taken into consideration, instead, a selection process should take place. Relevant knowledge is the knowledge that might contribute to innovation and, therefore, organizational performance (Cohen and Levinthal, 1990; Jansen et al., 2005). Moreover, in order for a firm to gain and maintain a competitive advantage, it is crucial that external knowledge is acquired quickly—or, at least, quicker than other competitors.

The ICT industry is very rich with "cases" of exploration and exploitation of technology-related knowledge (and associated issues). In this chapter, we would like to use the example of Facebook's recent acquisition of Instagram and the processes that supported the implementation of Instagram's functionalities into the Facebook portal and led to Facebook's users exploiting the new software (i.e., the software from Instagram).

Instagram, before being acquired by Facebook, was a start-up company that provided a set of tools to automatically upload and share photos on personal websites. Some of Instagram's features help users to graphically modify photos so that even those users who are not very familiar with photo-editing software (such as Photoshop®) are able to create amazing graphical effects.

In April 2012, Facebook acquired Instagram. From an absorptive capacity perspective, we can say that Facebook boundary spanners identified the start-up company whose business was tightly related to one of the main functionalities of Facebook—uploading personal photos to one's profile. After the identification of Instagram as a potential acquisition, communication between the board and the Facebook CEO (Mark Zuckerberg) took place. Shortly after, the decision to acquire Instagram was made and took less than a week to complete. Of course, at Facebook, both the boundary spanners and the board (in particular, Mr. Zuckerberg, who has considerable decision power in Facebook) had a background knowledge that allowed them to evaluate the external knowledge. That is, knowledge acquisition happened through boundary spanners, and decisions were made by powerful people in the organization (CEO and the board). How successful this acquisition will be in the long term is difficult to judge, but the case does illustrate a very swift process of (knowledge) acquisition, which is associated by some with competitive advantage (Argote and Ingram, 2000).

Knowledge assimilation includes processes of analysis and interpretation of external knowledge (Sun and Anderson, 2010). Knowledge assimilation can occur informally (through social networks) or formally (with the use of coordinators) (Zahra and George, 2002). Drawing again from the Facebook example, after the acquisition Instagram's technology was incorporated into Facebook's portal, moreover, Facebook users were "trained" on how to use the new service and connect it to their Facebook webpage. At Facebook, knowledge assimilation occurred once the technicians were able to make the new software available to the users; moreover, the marketing department identified effective ways to "sell" Instagram to Facebook users. Thus, while knowledge identification involved just senior management, knowledge assimilation involved technical and nontechnical processes and business units to make the new knowledge available for the users (with Facebook "customers" (i.e., the users) seen as part of the same—at large—community where absorptive capacity assimilation takes place).

In sum, both knowledge acquisition and assimilation are driven by prior knowledge; consequently, potential absorptive capacity is path-dependent (Cohen and Levinthal, 1990; Lane et al., 2006). This suggests that potential absorptive capacity is a combination of exploratory processes that can be effectively analyzed using the epistemology of possession. In fact, it is emphasized (in line with Lane and Lubatkin, 1998) that once the external knowledge is sufficiently similar to the knowledge of the potential recipient, identification and assimilation occur relatively easily. Moreover, it is quite common that the recognition and assimilation of knowledge are undertaken by individual actions rather than collective efforts, as per the Facebook example (i.e., boundary spanners and upper management identified new external knowledge and some technicians made the knowledge available for users).

Finally, the boundaries between Facebook and the environment (in the case of knowledge identification) and between Facebook and the users (in the case of knowledge assimilation) were syntactic and semantic. Syntactic boundaries were (easily) overcome in the case of knowledge identification: The knowledge related to Instagram (and its functionalities) was straightforwardly transferred to the Facebook technicians. On the other hand, syntactic boundaries were overcome when the functionalities of Instagram were made available to the worldwide Facebook users (i.e., with basic communication to the users and the translation in multiple languages of essential to-do lists on how to use the new photo-editing software and on how to manage and automatically upload the photos on one's Facebook's profile). Moreover, semantic boundaries existed (and were overcome) when the technicians were able

to incorporate the characteristics of Instagram into the Facebook portal to make the new service easily accessible by the users. As previously highlighted, once a relevant amount of prior knowledge overlaps the external knowledge, syntactic and semantic boundaries can be overcome without major challenges. Lane and Lubatkin's (1998) study on "relative absorptive capacity"—that is, knowledge transfer between two firms, one "learner" organization (the donator of knowledge) and one "student" organization (the recipient)—suggests that the more the overlapping knowledge between two firms, the more the process of knowledge transfer is straightforward.

17.5.3 Issues Associated with Knowledge Acquisition and Assimilation (Potential Absorptive Capacity)

From the preceding text, it is clear that knowledge acquisition and assimilation (potential absorptive capacity) are affected by path dependency. That is, an organization is likely to acquire knowledge that is similar to the knowledge it already knows. Once the acquisition of some particular knowledge starts, the organization is likely to keep trying to acquire similar knowledge in a particular area. In the following text, we discuss some of the most common issues that can occur within the process of knowledge acquisition and assimilation (potential absorptive capacity).

Issue 1: Context specificity of knowledge. Knowledge identification and assimilation can be difficult when external knowledge incorporates context-specific characteristics (Carlile, 2004) that often prevent outsiders from understanding and replicating such knowledge; for instance, as noted earlier in this chapter, Szulanski (1996) calls it "stickiness."

Issue 2: Complementary assets. Identifying and assimilating external knowledge can be difficult when the value of knowledge is associated with the existence of complementary assets that might not be available in the recipient firm (Teece, 1981; Zahra and George, 2002).

Issue 3: Prior knowledge and incremental innovation. One could argue that the very close relationship between prior knowledge and external knowledge might represent a hindrance to the implementation of disruptive innovation (Christensen, 1997). Namely, along with the idea that organizations are good when pursuing incremental innovation (Facebook improved an existing functionality of the platform—in fact, it was already possible to upload photos, even if with a more complex process), managers are less likely to identify knowledge that creates breakthrough innovation.

Issue 4: Power. Another issue that can be associated with potential absorptive capacity and, therefore, with the identification and assimilation capabilities is power. The idea that power affects managing knowledge is not new (Argote et al., 2003; Marshall and Brady, 2001; Pfeffer, 1981). While, in the previous sections, we highlighted that knowledge can lead to power (Bartol and Srivastava, 2002), here we also show how power can affect knowledge absorption (Easterby-Smith et al., 2008). In the literature on absorptive capacity, for instance, Todorova and Durisin (2007) focus on why some firms develop more absorptive capacity than others and suggest that power affects the extent to which organizations are able to explore external knowledge. This is interesting because it suggests that (few) people exercise power in organizations regarding decision-making processes that involve the introduction of technological innovation based on external knowledge. For instance, Marabelli and Newell (2009) document the case of an enterprise resource planning (ERP) implementation that initially was led by some managers from the adopting firm's sales department: they decided which system to implement, when to start the implementation, and with which characteristics (a lot of customization, in their case). One negative consequence of the exercise of power by just a few organizational actors was that while the recognition process was conducted very quickly, the assimilation phase—actual introduction of the system in the organization—encountered a number of technical and nontechnical problems. Differently from Facebook and Instagram, in this example, (Marabelli and Newell, 2009) power acted as a barrier (rather than a source of competitive advantage) to knowledge identification and assimilation.

In sum, we can conclude that, although recognizing and assimilating external knowledge can be seen as straightforward, a number of obstacles can occur: External knowledge can be associated with other invisible assets that are needed to fully understand new knowledge; since external knowledge is often very similar to the knowledge that an organization already has, radical innovation is limited; and power relationships can also affect potential absorptive capacity. In terms of power, the effects can be either positive or negative and this probably depends on the core competences of the leaders who exercise power: In the case of Facebook, Mr. Zuckerberg is a visionary innovator; in the case of Alpha Co. (the example in Marabelli and Newell, 2009), the management was probably not so skilled to make decisions regarding how to introduce a new ERP system.

17.5.4 Realized Absorptive Capacity

Within realized absorptive capacity, two main capabilities are identified: knowledge transformation and knowledge exploitation (Zahra and George, 2002).

Knowledge transformation is the ability to combine existing knowledge and the newly acquired and assimilated knowledge. This can occur by adding or deleting knowledge or by interpreting existing in-firm knowledge in light of external inputs. Zahra and George, drawing from Koestler (1966), depict knowledge transformation as a process where organizations recognize two apparently incongruous sets of information (external knowledge and in-firm knowledge) and are able to combine them to arrive at a new schema. Knowledge transformation capabilities are needed for strategically managing organizational change. During the transformation phase of absorptive capacity, knowledge has to be shared internally since business units' coordination, cross-division communication, and integration processes facilitate knowledge flows (Van de Bosch et al., 1999). Zahra and George's conceptualization of knowledge transformation (at least the way it is interpreted in this chapter) is very similar to Carlile's discussion on pragmatic boundaries (he also refers to knowledge transformation) and to Latour's idea of knowledge translation—that is, knowledge needs to be, to some extent, recreated or reproduced by those who are practicing it.

Bringing up again the case of Facebook (and Instagram), we can identify processes that can be linked to knowledge transformation. For instance, once the main technical problems were solved (the incorporation of Instagram's functionalities into the Facebook portal), and once a marketing campaign was conducted to inform the Facebook users about the availability of a new photo-editing/uploading tool, a more challenging issue emerged: The external knowledge (e.g., Instagram, and how photo digital editing can work for "dummies") had to be acknowledged by the users as interesting, appealing, and helpful. The literature on the introduction of new technology highlights that if the users are aware of its benefits they are also more likely to adopt it (Ferneley and Sobreperez, 2006; Hwang and Thron, 1999). And this is what happened at Facebook: In the phase of knowledge assimilation, Facebook put a lot of effort into informing the users of the benefits of Instagram for uploading photos on their personal pages. However, having the users adopt the technology is not an automatic process (Easterby-Smith, 2008). In fact, while tasks such as the Marketing department promoting innovation can be relatively straightforward, the actual adoption of technology requires more complex elaboration of external knowledge (Elbanna, 2006) that, as we argue in this chapter, requires in-context practice. This means that it is not just that the users need to be aware that some new functionality is available; they must be able to incorporate the novelty into their current routines. So, basic processes such as taking a picture with the IPhone and uploading it using the "photos" functionality available in the IPhone–Facebook "app" is replaced with taking the picture and using the "Instagram" functionality (still available as an iPhone app). Initially, moving from a familiar photo-editing and upload system to a more innovative system will be perceived as a more complex way to have photos on one's personal page; users need to become familiar with a different way to process pictures and this can take time and needs practice. The driver that makes the change happen is the user's belief that a process, which seems relatively complex, will be more "productive" in the long term (i.e., it is more powerful and adds new functionalities such as for-dummies image editing features).

Moreover, the new knowledge (again, Instagram) is shared among groups within social networks, based on virtual word-of-mouth (Gruhl et al., 2004). The way the Facebook portal is designed allows

others to see which application was used to create a photo that was shared, stimulating people's curiosity and creating the willingness to try a new, potentially interesting service. Users are then able to evaluate the new "tool" through practicing it. For users, moving to Instagram does not imply that they have to use it every time they want to upload a photo. Therefore, users may perceive that it is worth trying the tool. Online discussions can be seen as virtual communities of practice (Dube' et al., 2005) where new external knowledge is collectively combined in an online forum of practice.

Knowledge exploitation is the capability that allows organizations to actually apply the previously transformed knowledge for commercial purposes (Cohen and Levinthal, 1990); successful knowledge exploitation includes refinement, extension, and leverage of existing competences and creation of new ones by incorporating external knowledge into existing organizational processes and procedures (Tiemessen et al., 1997).

The successful knowledge exploitation at Facebook occurred when new users started to use Instagram. Knowledge exploitation can take time; in fact, as previously highlighted, Facebook users needed to practice the new tool for a while before deciding that it was better than the old system to upload photos. Moreover, at the time of writing, knowledge exploitation processes are still ongoing at Facebook.

Nevertheless, some conclusions can be drawn: First, effective knowledge exploration can lead to successful knowledge exploitation. Even if we do not argue that knowledge acquisition, assimilation, transformation, and exploitation can be represented as a linear series of processes, it is evident that only the acquisition of relevant knowledge can lead to its assimilation (because the firm has the skills to implement it into existing routines and processes; Zahra and George, 2002). Moreover, only effective assimilation (i.e., knowledge integration) leads people to (try to) practice new external knowledge with the aim to translate it and, consequently, to exploit it for commercial use (Cohen and Levinthal, 1990).

The preceding text suggests that during transformation and exploitation processes, knowledge should be collectively "practiced." Consequently, an epistemology of practice should be used to investigate realized absorptive capacity. Moreover, in the case of knowledge transformation, knowledge-sharing boundaries are pragmatic: As indicated in Carlile (2004), shared artifacts and methods play an important role in achieving the capacity to negotiate interests and transform knowledge. This is particularly evident in the Facebook example where the users have the possibility to see others' activities (i.e., somebody who was an early adopter of Instagram) and send positive feedback ("I like it" or "I don't like it") through the online portal (Facebook).

17.5.5 Issues Associated with Knowledge Transformation and Exploitation (Realized Absorptive Capacity)

Although effective knowledge identification and assimilation can lead to successful knowledge transformation and exploitation, realized absorptive capacity can encounter problems. In the following text, we list common issues related to the effective transformation and exploitation of new external knowledge.

Issue 1: Barriers to knowledge sharing. Knowledge transformation and exploitation are negatively affected by (potential) barriers to knowledge sharing. Since knowledge transformation happens through practice, people can benefit from the possibility of interacting with and discussing the new knowledge. It is important that users' experiences are shared among other users so that social processes of knowledge reproduction take place. Moreover, knowledge exploitation is the collective effort of implementing novelty into organizational routines so that the whole organization benefits from external knowledge (Zahra and George, 2002). Therefore, cross-unit barriers need to be overcome and clear common objectives identified. Pragmatic boundaries can make this difficult.

Issue 2: Long-term processes. Knowledge transformation and exploitation often require long-term practice (Lane et al., 2001) for the external knowledge to be recreated in the form of working knowledge. It is arguable that transformation capabilities are achieved in particular organizational settings such as communities of practice where frequent member interactions (as happens between Facebook members, Ellison et al., 2007; Wilson et al., 2009) allow both the appropriation of the new knowledge and

the creation of new knowledge using ideas from external inputs. However, short-term objectives and the rush to transform inputs (i.e., external knowledge) into tangible outputs (i.e., innovation, therefore performance) do not always promote knowledge transformation processes.

Issue 3: Power. Power affects knowledge transformation and exploitation. Given that both capabilities should be developed through practice, Nicolini (2011) points to the importance of addressing power issues. Moreover, Newell et al. (2009) noted that, although ideally organizational actors will channel their efforts to successfully share (and eventually transform) knowledge, this is quite a simplistic view of organizations. Assuming that common goals are always clear to employees is a very functionalist view of organizations (Burrell and Morgan, 1979). On the contrary, empirical results (Perez-Bustamante, 1992; Wagner et al., 2002) indicate that very often encouraging employees to surrender their knowledge for the benefit of the organization has the result of disempowering them. This is one reason why individuals might choose to "hoard" rather than share knowledge. Knowledge exploration too can be (often negatively) affected by reflecting interests of powerful groups. For instance, in large-scale projects of ERP implementation, it is not infrequent that decisions of powerful coalitions on how to exploit external knowledge result in a failure of the overall implementation of the external knowledge (the ERP system) (Kholeif et al., 2007; Yusuf et al., 2004).

As with potential absorptive capacity, then, realized absorptive capacity also presents issues because although effective knowledge exploration *can* lead to successful knowledge exploitation, this is not necessarily a straightforward process. Realized absorptive capacity requires practice for external knowledge to be transformed, and this practice is likely to throw up various problems because it can conflict with previous ways of doing things. This indicates that power issues may emerge during this period of transformation. Power relationships, thus, affect both potential and realized absorptive capacity. Our examples indicate that while power and successful potential absorptive capacity are mediated by the skills and experience of powerful decision makers (i.e., Mr. Zuckerberg), for realized absorptive capacity, the transformation and application phases are less likely to be fully controlled by dominant coalitions. Instead, emergent interactions among users (in this case, Facebook users) take place, which influence whether and how the knowledge is transformed and exploited. This is also consistent with the unpredictable nature of knowledge, spelled out by scholars who theorize from the practice perspective (Chia, 2003; Feldman and Orlikowski, 2011; Sandberg and Tsoukas, 2011).

In conclusion, we believe that the absorptive capacity construct is appropriate to provide a theoretical lens to clearly identify processes of knowledge exploration and exploitation. We acknowledge that absorptive capacity depicts these processes as being very linear: knowledge exploration, therefore, knowledge exploitation. This might not be what actually happens in organizations when they try to deal with processes of transformation of external knowledge into innovation. For example, the literature on innovation shows that a number of iterations, failures, and lessons learned might be needed (Dougherty and Dunne, 2011). However, we argue that the absorptive capacity construct is useful to graphically represent some knowledge processes that might occur when organizations strive to pursue innovation. Drawing from the Facebook example, we propose a synthesis of these processes in light of absorptive capacity, which are depicted in Figure 17.1.

Figure 17.1 highlights that there are different types of external knowledge and that the knowledge that is identified is likely to be similar to the knowledge that organizations already know (recognition capability); once some specific knowledge is identified as "potential," the organization needs to (quickly) implement it into existing routines. Firstly, technical implementation occurs (assimilation), and secondly, organizational actors (the "users" of the new knowledge) need to actually adopt the innovation and, we argue, this happens through practice (transformation); practicing the new knowledge might result in the creation of new "working" knowledge which is, eventually, fully exploited (i.e., the new knowledge becomes part of daily routines).

The absorptive capacity construct and, in particular, the tension between potential and realized absorptive capacity is also linked to other knowledge "elements" and metaphors that were discussed previously in this chapter (i.e., the repository view vs. the network view). Therefore, the aim of the next

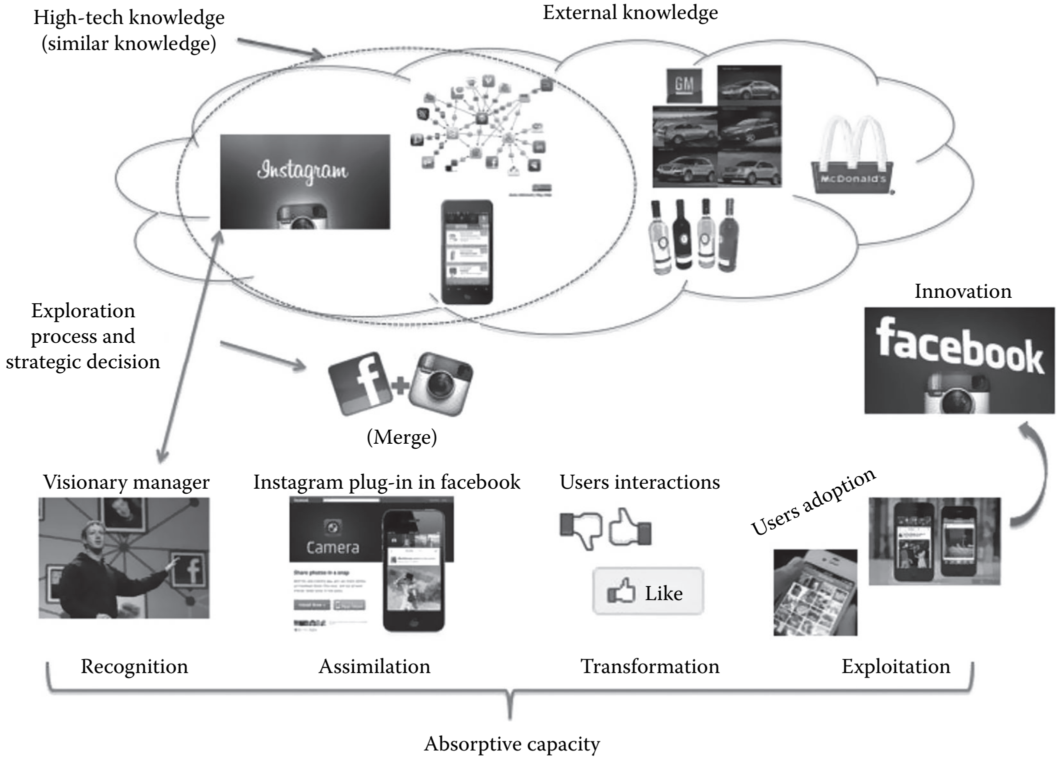

FIGURE 17.1 Example of absorptive capacity processes.

section is to synthesize the aforementioned and to suggest a comprehensive framework of knowledge that highlights the tension between exploration and exploitation under the umbrella of the epistemology of possession and the epistemology of practice.

17.5.6 Combining Potential and Realized Absorptive Capacity: The Mutual Constitution View

It is now clear that both exploration and exploitation processes coexist within a firm. Interpreting knowledge exploration and exploitation with the lens of absorptive capacity also suggests that while potential absorptive capacity can be interpreted with the lens of the epistemology of possession (emphasis on individual decision makers who own knowledge and emphasis on knowledge that is transferrable), realized absorptive capacity is better interpreted with the lens of the epistemology of practice. On the one hand, the epistemology of possession suggests that knowledge is owned by individuals and can be easily transferrable using ICT artifacts such as centralized databases and electronic archives (repository view); this is particularly true for potential absorptive capacity, as per our examples where the processes of knowledge *recognition* and *assimilation* were straightforward because syntactic and semantic boundaries can be easily overcome. On the other hand, the epistemology of practice indicates that some knowledge is also embedded in everyday practices; the main consequence is that it might not be sufficient to "store" knowledge in some repository to have it transferred to others. Instead, in this second case (practice perspective), knowledge is equated to practice (Nicolini, 2011) and, therefore, knowledge is *transformed* through negotiations (pragmatic boundaries) in order for the knowledge to be fully *exploited*. The network view and the realized absorptive capacity are, therefore, more appropriate concepts to represent these processes.

TABLE 17.3 Managing Knowledge: A Comprehensive Framework

Epistemology	Views	Ways of Sharing	Boundaries	AC View	Articulations
Possession	Repository	Transfer	Syntactic	Exploration	Acquisition
			Semantic		Assimilation
Practice	Network	Transformation ((re)production)	Pragmatic	Exploitation	Transformation
					Exploitation

Table 17.3 synthesizes the earlier theorizing and examples that are collapsed into a comprehensive framework of knowledge that considers epistemologies, views, ways of sharing it, and absorptive capacity capabilities.

From Table 17.3, it emerges that knowledge can be seen both as a possession (knowledge can be "moved about" within and between organizations) and as a practice. This is in line with the mutual constitution view that was illustrated in the first part of this chapter.

Interestingly, the mutual constitution view requires multilevel analyses. The possession view discusses both individual and organizational knowledge. For instance, Nonaka's (1994) SECI (Socialization, Externalization, Combination, and Internalization) process of knowledge conversion (from tacit to explicit) discusses the individual as well as the organizational level. However, the underlying assumption is that knowledge is "exchanged" among organizational actors (using socialization processes) and, therefore, the very nature of knowledge lies in individuals. The practice view discusses both individual and organizational knowledge. In fact, even if the emphasis is on collective knowledge that originates with practice, individuals can affect knowledge processes (being part of a community of practice, if we adopt the containment view, or being "actors that act in practice" (D'Adderio, 2006) if we adopt the radical view). This is highlighted by concepts such as consequentiality (Feldman and Orlikowski, 2011): An action is considered to be a practice when it is consequential for the development of the activity. Therefore, it is implicitly acknowledged that individuals can "actively" affect practices. Another concept from the practice view that highlights the role of individuals is the "nexus of practices," which indicates that a link between (individual) actions exists and that some actions might "matter more" than other actions (i.e., power relationships play a role in action). However, although these two examples highlight that the practice epistemology of knowledge considers individuals, the main focus of this epistemology is on collective processes. Thus, even while individuals matter from the practice epistemology, knowledge does not lie in an individual's mind but rather in their practices, which are always undertaken in conjunction with other actors (whether human and/or material actors). In conclusion, combining the epistemology of possession and the epistemology of practice is helpful for exploring knowledge processes from a multilevel perspective which, in turn, is helpful for fully exploring knowledge management dynamics (Hannah and Lester, 2009).

17.6 Future of Knowledge Management

Some have argued that KM is a fad, just like there have been many other fads related to ICT adoption in organizations (Swan et al., 1999). We would argue that while the term KM may not survive, the focus on improving ways to explore and exploit knowledge in organizations will not diminish. Indeed, while traditionally organizations were either designed to maximize efficiency or flexibility (Thompson, 1967), today organizations are exhorted to be "ambidextrous" (Adler et al., 1999; Newell et al., 2003; O'Reilly and Tushman, 2007; Tushman and O'Reilly, 1996). Being ambidextrous requires a focus on both exploitation (to constantly increase efficiency of what the organization is currently doing) and exploration (to increase flexibility through innovating in products, services, or organizational processes). In the past, as we have seen, much KM effort has been on the exploitation aspect, with organizations introducing document management systems, searchable databases, and intranets so that people can more effectively share

and so exploit the knowledge that already exists within an organization. In the future, we anticipate that a similar level of effort will be placed on exploration, using social networking and other multimedia technologies that can help to connect people. Such social network-based online platforms (Facebook-like technologies for use within an organization) that focus on collaboration and cross-fertilization among different business units can help organizations develop informal ways to share information and knowledge to promote innovation. These types of KMS can help to stimulate the development of (virtual) communities of practice that bring together people from different locations, and so take advantage, potentially, of talent that is globally distributed (Dube' et al., 2006).

It has been demonstrated that innovation leads to long-term competitive advantage and that interactions (i.e., knowledge exchanges) among people with different backgrounds and skills can help to promote innovative and disruptive ideas (Desrochers, 2001; Hanna and Walsh, 2002). Therefore, in the past, a lot of attention was given to organizational design, structuring processes so that departments would communicate at least for specific initiatives, for example, product innovation involving marketing, sales, and R&D, and cross-unit process innovation involving different business units (Hansen and Birkinshaw, 2007; Martin and Eisenhardt, 2010). Moreover, strategic links between organizational actors such as project managers, process managers, product managers, and so on were put in place. Nowadays, organizations are less bureaucratic and more network-based (Borgatti and Foster, 2003; Capaldo, 2007), that is, they do not try and undertake all activities but rather work with other organizations who may be better placed to provide particular types of service, as with outsourced IT service provision. This network will typically be globally distributed and rely heavily on ICT for information and knowledge sharing. Along with dealing with syntactic and semantic boundaries (i.e., different languages and therefore difficulties in communicating to exchange basic information; time change differences; cultural and background differences), overcoming pragmatic boundaries are likely to be the most challenging issue KM (and KMS) face. That is, worldwide dispersed units of a networked organization need to be able to collaborate online and create synergies that are typical of localized communities of practice. While, from a technical point of view, effective online platforms that allow video meetings/conference calls already exist, people are now learning how to use ICT as a substitute for face-to-face relationships. While such virtual relationships can be very seductive (as evidenced by the amount of time people spend on sites such as Facebook and Twitter, as well as in online gaming sites), questions remain about differences between online and face-to-face relationships and their respective impact on our social world.

17.7 Conclusions and Implications

In this chapter, we aimed to provide an overview of knowledge and its exploratory and exploitative nature (*What is knowledge?*) with respect to two different epistemologies that relate to different approaches to managing knowledge: the epistemology of possession (*repository view*) and the epistemology of practice (*network view*). We then highlighted that, today, technology plays a role in supporting knowledge processes (*technology for support of KM processes*), and we suggested that the absorptive capacity construct could be adopted to highlight knowledge exploration and exploitation processes (*knowledge exploration and exploitation*).

We concluded arguing that the mutual constitution view (a "generative dance," Cook and Brown, 1999) is an effective representation of KM processes and can be linked to potential and realized absorptive capacity. Moreover, we noted that adopting a mutual constitution view allows multilevel analysis: Individuals possess knowledge generated by engaging and investing in (collective) practices. Finally, adopting the mutual constitution view of knowledge has implications for technology: For instance, while the possession perspective indicates that data sharing and centralization (e.g., using ERP architectures) has several advantages for creating an organizational memory (Vandaie, 2008), the practice perspective highlights that technology can be fully exploited only if the "users" actually adopt and use IT artifacts in their practices (Feldman and Orlikowski, 2011).

18.1 Theory

In his book "Libraries of the Future," J.C.R. Licklider predicted that a world network of automated libraries would together support global information requirements, supported by a hodgepodge of different technologies, since there was no integrated theory (Licklider 1965). After more than 40 years, it has become clear that advances in understanding and technology have allowed a theory-based approach to this field that should aid those interested in computer science, information systems, and/or information technology to better grasp the key concepts regarding digital libraries (DLs).

18.1.1 DL Definitions

Though storing and retrieving information with the help of computers dates back at least to the 1950s (Taube 1955), those focused on what has emerged as the field of DLs did not select that phrase until about 1991, giving it preference over terms such as electronic library or virtual library.

Accordingly, some have been interested in defining what constitutes a DL as a step in clarifying its particular place in the digital world. Three illustrative examples of such definitions follow:

1. "A digital library is an assemblage of digital computing, storage and communications machinery together with the content and software needed to reproduce, emulate and extend the services provided by conventional libraries, based on paper and other material means of collecting, cataloging, finding and disseminating information" (Gladney et al. 1994).
2. "A set of electronic resources and associated technical capabilities for creating, searching and using information. In this sense they are an extension and enhancement of information storage and retrieval systems that manipulate digital data in any medium (text, images, sounds; static or dynamic images) and exist in distributed networks. The content of digital libraries includes data, metadata that describe various aspects of the data (e.g., representation, creator, owner, reproduction rights) and metadata that consist of links or relationships to other data or metadata, whether internal or external to the digital library" (Borgman 1996).
3. "Digital libraries are a focused collection of digital objects, including text, video and audio along with methods for access and retrieval and for selection, organization and maintenance of the collection" (Witten and Bainbridge 2002).

18.1.2 Digital Library Curriculum

By 2005, many DLs were in widespread use, providing increasingly popular means of collecting and finding information. It became clear that educational and training support was needed for the emerging community of digital librarians. Toward this goal, a team at Virginia Tech and the University of North Carolina at Chapel Hill collaborated to develop a curriculum, founded in theory and practice, that could be used to teach about DLs in library schools, information science departments, or computer science programs (Pomerantz et al. 2006). Figure 18.1 gives one perspective on how some of the modules that have been developed could be used in a two course sequence; it also demonstrates many of the key topics associated with DLs. An increasing number (already more than 40) of learning modules, each supporting either self-study, tailored training, or roughly a week of coverage in a course, can be accessed both through Wikiversity and our website (Fox et al. 2012b).

18.1.3 Formal Approaches

In computing, rapid advances often follow the development of a theory that enables a formal approach to practical problems, for example, the use of the relational model for databases (Codd 1970). In the DL field, early efforts ignored the use of formalisms, so the availability and features associated with services were haphazard. Clearly, the community of DL producers can benefit from formal definitions of existing and proposed DLs, along with the services they provide. Formalisms within the field of DLs provide a theoretical foundation. This can save work for designers and implementers, for example, by enabling the reuse of formally and programmatically defined services, and the deployment of existing service modules in the generation of proposed DLs for a specific context. The two major efforts toward a theoretical framework include the 5S formal framework (Goncalves et al. 2004; Fox et al. 2012a) and the DELOS reference model (Candela et al. 2011).

18.1.3.1 5S

The 5S (streams, structures, spaces, scenarios, and societies) framework builds on five precisely defined yet intuitively understandable basic constructs, allowing a high level foundation to be used to describe all key DL concepts (Fox et al. 2012a). Streams encompass sequences of information that represent content. Streams include audio, video, bit streams on disk or transmitted over a network, and character strings that constitute text. Structures represent any type of organization (e.g., a database, taxonomy, thesaurus,

FIGURE 18.1 Curriculum modules by semester.

dictionary, ontology, data structure, record, file in a particular format, or any digital object following some type of schema) and can be described using labeled graphs. Spaces are sets of items along with rules and operations valid for each set of items. In addition to the usual 1D, 2D, and 3D spaces, there are vector, probabilistic, and topological spaces. Typical user interfaces are implemented on a 2D space, while many search engines are based on a vector space model. Scenarios are sequences of events that lead to an outcome. All services follow scenarios, as do workflows, procedures, and algorithms. Societies are made up of entities, either human or computing-based, with relationships among them. Thus, they encompass the set of end users, groups engaged in collaboration, social networks, and other aggregates studied in psychology, the social sciences, or fields like law or economics. As can be seen in Figure 18.2, each of the five constructs can be used alone or in combination with the others to define every one of the key constructs we consider to be required parts of even the most minimal DLs.

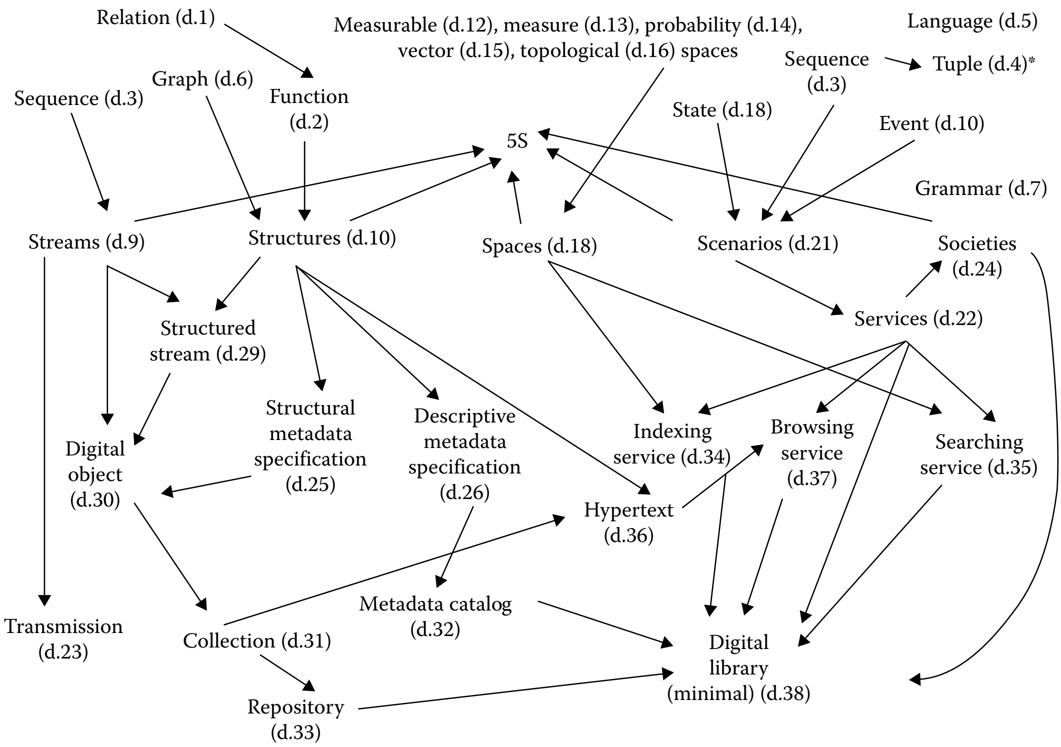

FIGURE 18.2 Formal definition dependencies for the constructs of a minimal digital library. (Reprinted from Goncalves et al., *ACM Trans. Inform. Syst.*, 22(2), 270, 2004.)

The 5S formal framework also may be used to encode descriptions of DLs and related concepts. Common services required by a range of DLs were initially defined, for example, indexing, searching, browsing, and annotation (Goncalves et al. 2008). The framework has since been extended to describe concepts found in a number of different domain-specific DLs (Murthy et al. 2007). Such extensions allow for emerging classes of DLs to be formalized, for example, for content-based image retrieval (Murthy et al. 2011) and scientific workflow systems (Leidig et al. 2010). Definitions of new services or aspects to DLs may build on top of existing definitions, and producing formal descriptions of DLs is facilitated through reuse of the existing set of definitions. Additional research connected with 5S has produced tools to aid in developing DLs, involving quality evaluations (5SQual) (Moreira et al. 2007), a description language (5SL) (Goncalves and Fox 2002), and graphical representations (5SGraph) (Zhu 2002). The 5S framework has been used in multiple DLs including Networked Digital Library of Theses and Dissertations (NDLTD), electronic tools and ancient near east archives (ETANA), Ensemble, and scientific DLs (Fox 1999; Ravindranathan et al. 2004; Fox et al. 2006, 2010; Leidig et al. 2011).

18.1.3.2 DELOS

The DELOS digital library reference model aims to provide a foundation for describing, understanding, and evolving the field of DLs. The model describes the DL universe in terms of digital library management systems (DLMS), digital library systems (DLS), and DLs. A DL instance is a practically running system that is perceived and used by end users. A DLS is the software implementation of the required functionality of a class of DLs. A DLMS addresses a conceptual problem, provides a software solution, and implements a DL approach as given in formal definitions of architecture, content, functionality, policy, quality, and users. The reference model has been repeatedly updated to provide concept maps, definitions, and conformance evaluation checklists (Candela et al. 2011).

We believe that mappings could be defined between concepts in the reference model and the 5S framework, so either approach might be employed, depending on the situation at hand. However, we prefer (1) a bottom-up approach to theory development, with everything precisely defined; (2) starting from a minimalist perspective; and (3) growing the framework incrementally as needed. Hence, we focus on 5S and use it in the rest of this chapter.

18.2 Data, Information, and Knowledge

Content is an essential part of a DL. The computing-related fields generally view content from varied perspectives based on decomposition into three levels of abstraction or complexity: data, information, and knowledge. This is particularly useful since it encourages use of tailored services inside a DL, such as database management systems, search engines (sometimes based on information retrieval toolkits), and knowledge management systems (e.g., for managing ontologies). Yet, DLs also have simplified work with content by shifting focus to a different set of abstractions, discussed in the subsequent sections.

18.2.1 Digital Objects

In a DL, the simplest abstraction for an element of content is to consider it as a digital object. Clearly, with the help of computers, much content is created in a digital form, like this chapter. Nevertheless, there are myriad objects in the real world that are not in digital form, such as physical books, paintings, statues, buildings, chemical or biological samples, and mathematical constructs. Fortunately, building on practices in linguistics and information science, we can discuss such objects if they are assigned a name, identifier, descriptor, and/or surrogate (e.g., a photograph or image prepared by a scanner). Thus, we can simplify the discussion of the content of a DL if we assume that anything of interest has some associated digital representation, allowing us to focus solely on such digital objects.

18.2.1.1 Atomic/Complex

There are many types of digital objects that can be stored in a DL. Some basic types include text, image, audio, and video. Each of these types has different formats and structures, for example, text formats include web pages, PDF, XML, or any file that contains a stream of characters. Digital objects also can be categorized based on the complexity of the structure of the object as either atomic or complex. Atomic objects are the basic unit of storage in a DL. All the basic types can be considered atomic objects. Basic types cannot be decomposed into smaller objects. Complex objects are objects that are composed of an aggregation of atomic objects into one unit with a certain structure that records the relationships between the different components (Kozievitch et al. 2011). Complex objects also can be constructed using parts of several other objects. Extending this notion further, we refer to the concept of extracting a part of an object (e.g., a sub-document) and treating it as a whole unit by itself, together with connecting together a set of such units, as superimposed information (Murthy et al. 2004). This approach provides a foundation for any type of annotation system and leads to a class of DLs that is particularly useful for a wide variety of scholarly activities (Murthy 2011).

18.2.1.2 Streams, Structures, and Spaces

These three constructs were briefly introduced earlier in Section 18.1.3.1. Their utility in describing the content in DLs needs further elaboration, however.

Streams are sequences of objects, for example, bits, bytes, characters, numbers, images, audio samples, and clicks. Thus, streams can be constructed from objects with different granularity levels. For example, a text is based on characters, while a book is based on pages. Streams may be static, as when a sequence of characters makes up a name or an abstract. Or, they may be dynamic, as in the stream of data that comes from a sensor or surveillance camera, or that is recorded into a log. In part to support all such dynamic streams, data stream management systems (Arasu et al. 2004) have been developed.

Structures also are essential in DLs. Understanding data structures, related algorithms, and their use (Shaffer 1997) is an essential basis for working with structures in DLs. This also aids the use of special languages used to describe structures, such as schema for relational databases, XML (Sperberg-McQueen and Thompson 2000) files/databases, or resource description framework (RDF) (Brickley and Guha 2004) (triple) stores. Of particular importance are record structures, commonly used for metadata (see Section 18.2.5). DLs support other important types of structures, such as classification systems, taxonomies, dictionaries, ontologies, databases, and hyperbases. Furthermore, when combined with streams, we have structured streams, which lead to constructs like documents, protocols (e.g., the organization of the streams connecting clients and servers), and files (that generally have some format or type, which specifies how the bytes are organized to carry meaning).

Spaces support representations that can help in organizing, retrieving, and presenting the content in a DL. One broad class relates to user interfaces that often adopt some spatial metaphor and connect some abstract spatial view with a concrete spatial instantiation (e.g., a window system). Another broad class relates to geographic information systems, often with time added as another dimension, supporting maps, timelines, global positioning system (GPS) data, mobile applications, studies of earth/atmosphere/astronomy, and combinations like mashups. A third broad class relates to multidimensional representations using various features that leads to particular implementations using vector or probability spaces, suitable for indexing, searching (especially approximate, nearest neighbor, cluster based, or range), retrieval, and ranking. An interesting example is an index that often is essential to ensure efficient operations of DLs; such an index generally combines streams of characters (for entries in the index), structures (to allow rapid response for key operations), and spaces (as in the vector space model).

18.2.1.3 Media

It is common for DLs to handle text documents with embedded images. But to address the broad needs of users around the world, DLs must support all types of content, including multimedia and hypermedia (multimedia with links), with sufficient quality of service, through speedy connections.

Multimedia has become an effective information sharing resource. DLs should provide direct support, including content-based searching, summarization, annotation, and specialized linking, as well as adequate storage (amounting to petabytes), for video, speech, audio, images, graphics, and animations. This is important, since web users expect services like those found with Flickr, Pandora, Shutterstock, YouTube, and Webmusic.IN. Sources of multimedia include libraries, museums, archives, universities, and government agencies, as well as individuals comfortable with uploading from cameras, smartphones, and camcorders.

Specialized DLs also support oral histories, recordings of dying languages (and translations), reuse of video segments, searching for similar images/videos, geo-coding, analysis of health-related images and data, support for bioinformatics, management of chemical information, access to tables and figures in documents, and preservation of virtual environments. Since formats keep changing in specialty areas, long-term preservation of such content is a particular challenge.

18.2.2 Collections

In a DL, a collection is generally an assembled, cataloged, and easily accessed digital information aggregation, whose resource data are usually provided through underlying database and storage structures (Unsworth 2000). Within a collection, storage preserves many kinds of digital information (such as documents and media files), which have been cataloged (see Section 18.2.5) and indexed for users' easy access. Thus, a collection is a set of digital objects, which may be atomic or complex, which may represent a variety of media and content types, and which should be accessible, such as by browsing (if in the form of a hyperbase) and searching (through an index and catalog). Within a collection, the format and class of digital objects generally is consistent in structure and representation. As an example, a book collection generally has associated descriptive information for each item in the collection, such as "title," "publication information," "material type," "call no," "location," "status," and "ISBN."

A DL may be made up of one or several collections. Minimal support for DLs that manage multiple collections involves supporting each one independently. Integration challenges must be addressed if a unified view is to be afforded across the collections. This can be further complicated when the DL provides portal services while storing key information for digital objects that are distributed (Fox et al. 2010).

18.2.3 Linking and Linked Data

As can be seen in Figure 18.2, a DL includes a hypertext collection, or, more generally, if there is multimedia content, a hyperbase. This links objects in the collection together and facilitates browsing. Additional capabilities may be provided, depending on the nature of the hyperbase and on related services; we can understand this more clearly in the context of the World Wide Web (WWW).

The WWW is a huge source of data that is linked into what is called a web graph. The nodes in the graph are web pages, while the edges (arcs) are the hyperlinks between those pages. The WWW is considered a dynamically linked graph, where the graph is rapidly increasing in size and the links are continuously being created and changed. Hyperlinks connect web pages for purposes of navigation, connectivity, and reuse. The relationships between linked web pages are unspecified, and their nature can only be guessed by studying the anchoring texts.

Hyperbases can be much richer and supported by more powerful services. For example, links can be bidirectional, and stored in a database rather than in objects themselves. Furthermore, links can connect either sub-documents or documents, so the nature of each of the origin and destination can be anywhere in the range from highly specific to very general. When the hyperbase includes content fitting with the RDF (W3C 2004b), a node in the hyperbase can be as small as a string that names something, while when multimedia is included, a node can refer to a large video. Since the WWW uses general addresses, a node can even be a website or database.

With linked data, the granularity often focuses on the small side. In PlanetMath (Krowne 2005), there is automatic linking from many of the words in each encyclopedic entry, so the number of links is very high, and connectivity is strong (Krowne 2003). Linking web pages based on the semantic concepts and relations between them is considered in the Semantic Web (Berners-Lee et al. 2001) approach. Examples of works with extensive linking include Wikipedia, DBpedia, and ontologies.

18.2.4 Semantic Digital Library

Incorporating semantics (machine-oriented representations of meaning) in DLs can be done at different levels and using different formats. Semantics can help enhance the organization of data, aiding interoperability, facilitating integration of different collections, enhancing and enriching the services provided, and providing a domain model for each collection managed by the DL. In keeping with the recommendations of the World Wide Web Consortium (W3C) and fitting with plans for the Semantic Web, at least two types of representations should be supported. The first is RDF (W3C 2004a,b), typically managed with some type of triplestore, as is used in the Cyberinfrastructure for Network Science (CINET) project (see Section 18.4.1). The second involves ontologies, as represented by the web ontology language (OWL) (W3C 2004a) or other schemes. One of the goals of the Ensemble system (see Section 18.5.3) (Ensemble 2009) is to use ontologies to aid access by stakeholders. Thus, instructors in business, teaching about databases, can make use of connections in the ontology to identify database-oriented educational resources in an Ensemble collection developed by computer scientists.

18.2.5 Metadata and Catalogs

Metadata provides information about one or more aspects of the digital objects stored in the DL, such as: how the data are created, the purpose of the data, time and date of creation, creator or author of data,

location on a computer network where the data resides, and standards enforced on the data. Many current DLs at least include content for each of the 15 specified metadata elements that constitute the Dublin Core metadata standard, which was developed to enable easy description of web content (Dublin-Core-Community 2002).

Metadata are valuable for information retrieval. If digital objects themselves cannot be accessed and indexed, the metadata may be the only information usable to enable exploration. Even when full text is available, often the subject description and other elements in the metadata description can be used to enhance retrieval. Accordingly, the choice of metadata scheme can affect how well the system can satisfy the user's information needs and greatly affects its long-term ability to maintain its digital objects.

Metadata records are stored in a catalog, so that every digital object has at least one metadata record in the catalog (or more if several metadata formats are supported). In some cases, the catalog is called a union catalog, when digital objects come from a variety of sources. A representative example is the union catalog of the NDLTD (2012).

18.2.6 Repositories

Repositories are a leading way of collecting, organizing, archiving, preserving, and providing access to intellectual properties. One important role is to have collections of metadata.

18.2.6.1 Institutional Repository

Institutions producing scholarly work often collect, store, and provide access to intellectual properties generated within the institution. These repositories often allow universal access to resources including theses and dissertations, courseware, and technical reports. Services of these repositories include cataloging, organizing, indexing, browsing, and searching. One of the main goals of these repositories is to archive and preserve the contents while providing long-term access to the material.

A number of software packages are available to help institutions set up and maintain digital repositories. DSpace, introduced by the DSpace Foundation (DSpace 2008), is an open-source software package used by a number of institutional repositories, in part, since it is easy to install and deploy. Other systems include Fedora (Staples et al. 2003), ePrints (EPrints.org 2002), and various open-source content management systems (CMSs).

18.2.6.2 Open Archives Initiative

Interoperability between different repositories is important for linking and cataloging resources across these repositories. Many DLs participate in the Open Archives Initiative (OAI) in order to ensure interoperability (Van de Sompel and Lagoze 2000). The OAI Protocol for Metadata Harvesting (PMH) is a standard for gathering metadata across DLs. Under OAI-PMH, actors fall into one of two roles, the data provider and the service provider. A data provider has a collection of metadata that it exposes through the protocol. A service provider then can provide any of a number of services (e.g., searching and browsing) from its local collection that is built through a series of requests for metadata (using PMH), sent to data providers. A number of open-source software packages such as jOAI (Weatherley 2012) and the collection workflow integration system (CWIS) (Internet Scout Project 2012) are available to allow repositories to expose their metadata following PMH.

The OAI also has aided interoperability through another initiative, OAI-ORE (Lagoze and Van de Sompel 2007), which focuses on object reuse and exchange. This operates in the context of the Semantic Web to enable interoperability involving groupings of information items (see Section 18.2.4). It addresses compound objects, such as those described using RDF, so those aggregations can be transferred between repositories, and used in each location.

18.2.7 Life Cycle

Content management involves more than the storage and retrieval of content. Policies and procedures are required to support content throughout its life cycle. A traditional life cycle describes stages like generation, management, use, change, and deletion (see Figure 18.3). Long-term aspects of content management include curation, archiving, and preservation. Curation involves deciding what content to maintain, under what conditions, and for how long. The following subsections discuss further the subsequent stages of archiving and presentation.

18.2.7.1 Archives

Archiving is the process of preparing, representing, and storing content to be accessed later. Key issues to consider include storage media, format representations, and access tools. A large number of physical and digital archives exist in a broad range of domains. Many countries have national archives, and there are special graduate programs for archivists.

18.2.7.2 Preservation

Preservation is the process of ensuring that the format, meaning, and accessibility of content are not lost over time. Various preservation operations may be performed on collections, for example, reformatting, copying, converting, migrating, and transforming. Physical media and content representations are changed periodically to keep up with the progression of technology. If the meaning and integrity

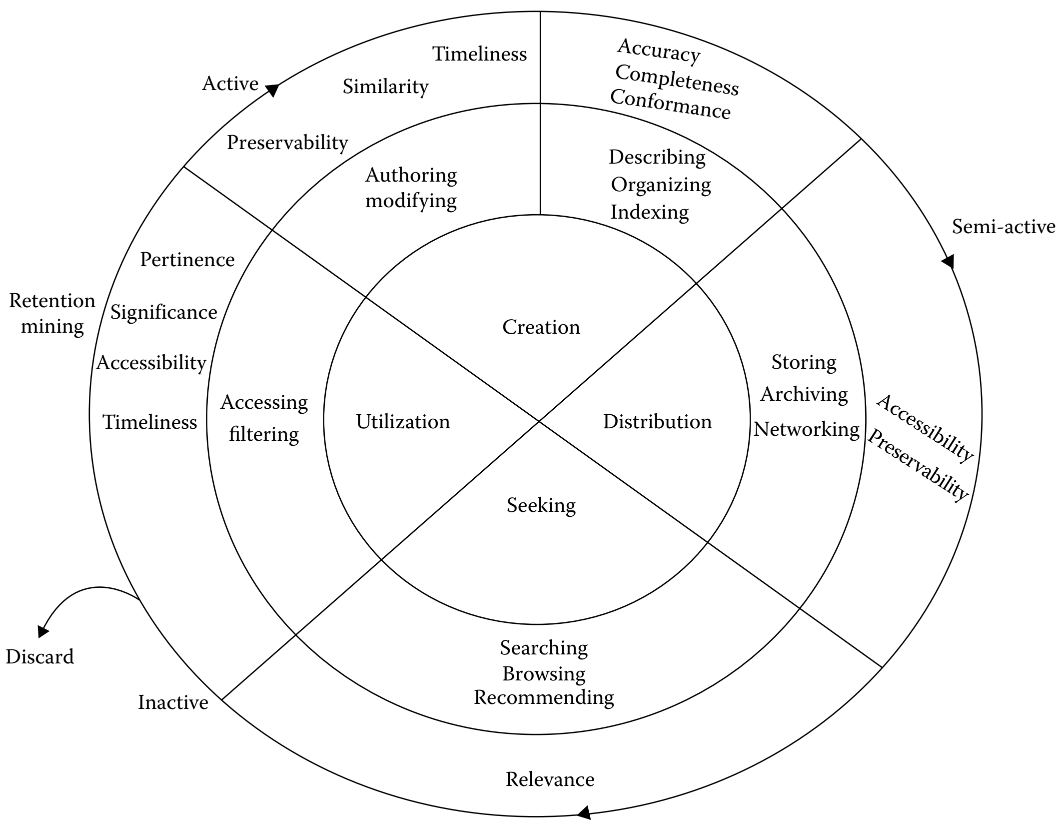

FIGURE 18.3 Life cycle quality on outer ring.

of content are not preserved, then content may be lost or may become inaccessible. There are a host of external threats to digital collections (Rosenthal et al. 2005). These include media failure, hardware failure, software failure, network problems, media and hardware obsolescence, software obsolescence, human error, natural disaster, attack by hackers, lack of funding to continue maintenance, and the demise of the hosting institution. Technology obsolescence complicates preservation services as computers and software are updated frequently and lead to the inability to access data. Technology fragility leads to inaccessible data when byte streams are changed or corrupted. Content should be examined periodically to mitigate some of these factors and ensure that bits have not changed, for example, using MD5 checksums. Duplication and replication techniques also are used to ensure an acceptable copy is available if a given copy is corrupted or lost, for example, using lots of copies keep stuff safe (LOCKSS) (Reich and Rosenthal 2001). Accessibility is provided through emulation, simulation, and translation from older software and operating systems.

The full information life cycle shown in Figure 18.3 includes the phases discussed earlier, along with others. For each phase, as can be seen in the outer ring, it is important to ensure that quality is maintained, so users interested in information at every stage have suitable services that address their information needs. This leads to a broader discussion of users, or, in 5S terms, societies, in the next section.

18.3 Societies

18.3.1 Users, Roles, Collaborators, and Communities

A DL serves a wide range of audiences including content authors, contributors, reviewer, editors, publishers, managers, content users, viewers, and readers. Individual users can be grouped into different categories based on their interest and use of the DL. Users with similar interests may form groups and communities within a DL. These groups can include reviewers, authors, editors, and members of organizations.

The need for access control on DL content can lead to systems supporting various roles for users. For example, while some users can be given the "Edit" privilege (i.e., an advanced role), other users may only have viewing privilege (i.e., a general role). A user may be assigned one or multiple roles based on factors such as ownership, activity level, and membership status.

User interactions such as tagging and ratings within a DL create a collaborative environment where community-added information enhances the value of existing content.

18.3.2 Social Networks

Social networks are becoming essential in different domains where collaboration is deemed important. Existing tools make it easier for DL users to share content on their preferred social networks (e.g., Twitter, G+, and Facebook). Systems used to manage DLs also are allowing users to create social networks within a DL. The existence of social networks can be leveraged to enhance the quality of services like rating and recommending (Ensemble 2009).

18.3.3 Intellectual Property

Societies follow a range of legal, social, economic, political, and other rules and regulations—these all connect to DLs in the 5S framework. One of the key areas associated with DLs that cuts across a number of these society-related issues deals with how content relates to its creators, disseminators, and users. Intellectual property (IP) concerns focus particularly on the origins of content, the ownership of economic interests, who has access (and under what conditions), and how all this is managed.

18.3.3.1 Open Access

Some DLs provide access to their content online, free of charge, and free of most copyright and licensing restrictions. Such libraries may be called open-access DLs. These are common in the case of institutional repositories and of other sites that are part of the OAI. However, sometimes access must be controlled, as is explained in the following section.

18.3.3.2 Digital Right Management, Security, and Privacy

Security is important to consider when designing certain types of DLs. Security weaknesses in DLs can be exploited to access confidential information, result in loss of integrity of the data stored, or cause the whole DL system to become unavailable for use. This can have a damaging effect on the trust afforded to publishers or other content providers, can cause embarrassment or even economic loss to DL owners, and can lead to pain and suffering or other serious problems if urgently needed information is unavailable (Fox and ElSherbiny 2011).

There are many security requirements to consider because of the variety of different actors working with a DL. Each of these actors has different security needs, which are sometimes in conflict; this can make the security architecture of a DL more complex (Chowdhury and Chowdhury 2003). For example, a DL content provider might be concerned with protecting IP rights and the terms of use of content, while a DL user might be concerned with reliable access to content stored in the DL.

Some content stored in a DL may not be provided for free. Many content providers are concerned with protecting their IP rights. They may employ digital rights management (DRM), which refers to the protection of content from logical security attacks and the addressing of issues relating to IP rights and authenticity. DRM provides protection by encrypting content and associating it with a digital license (Tyrväinen 2005). The license identifies the users allowed to view the content, lists the content of the product, and states the rights the users have to the resource, in a computer readable format, using a digital rights expression language or extensible rights markup language that also describes constraints and conditions.

18.4 Systems

Building upon the discussion of formal approaches in Section 18.1.3, we can explain how systems fit with DLs. According to the DELOS reference model (Candela et al. 2011), this can be considered in levels (see Section 18.1.3.2). Further details are given in the following subsections, beginning with a broader discussion to provide context.

18.4.1 Cyberinfrastructure

Cyberinfrastructure (CI) refers to a broad area of software and systems deployment to aid societies with computing solutions including automation and provision of desired services (Atkins et al. 2003; NSF 2007). DLs generally fit into this either as standalone or embedded systems. A standalone DL can be utilized to support information satisfaction in a web portal, provide an underlying storage system, perform logical control and organizational functions, and conduct domain-specific tasks. The AlgoViz case study discussed in Section 18.5.2 explains such a standalone DL with its own portal and management system. On the other hand, a DL can operate at the middleware layer, embedded in a larger environment, for example, to provide a variety of data management and complex services to support scientific tasks. This makes sense, since eScience systems are complex and contain a variety of computing components. In general, CI often involves user interfaces, communication protocols, distributed high-performance computing resources, instrumentation, software applications, repositories, content collections, and multiple societies and user types. The CINET case study in Section 18.5.6 explains about a DL that is fully integrated within such a larger CI.

18.4.2 Architecture

In the software world, the structural aspects of a system are referred to as architecture, which in the case of DLs can be quite varied (Fox et al. 2005), including whether the system is a monolithic entity or an interconnection of components or whether it is centralized or distributed. Varying approaches can be employed, such as using agents (Birmingham 1995) or having a service-oriented architecture (Petinot et al. 2004).

DLs from multiple institutions and domains can be combined into a single federated system (Leazer et al. 2000), even when constituent DLs span multiple organizations with related but often conflicting purposes, goals, content, formats, collections, users, and requirements. As such, integration and interoperability is needed between federated DLs. These actually are easier if harvesting replaces federated search (Suleman and Fox 2003). This use of harvesting was one of the initial contributions of the OAI, discussed earlier in Section 18.2.6.2. Thus, harvesting is used in the National Science Digital Library (NSDL, see Section 18.5.4), which connects multiple DLs serving a variety of science-related domains.

18.4.3 Building DLs

In general, the different phases that go into building a DL are (Dawson 2004)

Planning
Requirements gathering and analysis
Standards and policy making
Collection development
Architecture design
User interfaces
Metadata collection and enhancement
Classification and indexing
Implementation of services
Access management
Security/authenticity
Preservation
User studies
Evaluation

Many DLs have been built from scratch, or from general components, as we did with the Computing and Information Technology Interactive Digital Educational Library (CITIDEL 2001), Multiple Access Retrieval of Information with ANnotations (MARIAN) (France et al. 2002), and Ensemble (2009). Such custom efforts are important in large-scale DLs catering to a very specific audience. More common, however, especially in recent years, is to make use of readily available software products, toolkits, and generic systems like Greenstone (Witten et al. 2000) for developing DLs. Many such solutions, often open-source, now exist for building DLs. The most widely used ones are presented in the following text.

The Greenstone DL software was born out of the New Zealand Digital Library Project at the University of Waikato and is one of the most extensively used open-source multilingual software packages for building DLs (Witten et al. 2001, 2009). It is a comprehensive system for constructing and presenting collections of millions of documents including text, images, audio, and video. The runtime system of the software has two parts: the receptionist, which takes requests from clients, and the collection server, which is the communication channel between the receptionist and the database. Collections can be built by specifying the Uniform Resource Locators (URLs) to be crawled. The user interface can be customized by the user.

Other widely used software for DL construction include Fedora Commons and DSpace, both of which are managed by a nonprofit organization called DuraSpace. DSpace is a "turnkey institutional

repository" that is used for creating open-access collections of all types of media. It is used most commonly in academic institutions. Fedora Commons is a software platform for managing, storing, and accessing digital content. Due to its modularity, it can easily be integrated with other database systems. DSpace, being an out-of-the-box solution, is easy to use in small repositories, while Fedora Commons is a more robust suite of services for an advanced, completely customizable repository (Bagdanov et al. 2009).

18.4.4 Services

DLs carry out many scenarios, and, thus, provide varied services to societies. We discuss this broadly in the 5S context in (Fox et al. 2012a), including providing a comprehensive taxonomy of services and describing which services we believe should be built into any system that is called a DL. The key minimal services are discussed later in Sections 18.4.4.1, 18.4.4.2.1, and 18.4.4.2.2; the following discussion also sets the context for understanding additional DL services. Some services, like indexing (see Section 18.4.4.1), relate to having a suitable DL infrastructure, while others address societal needs (see Section 18.4.4.2).

18.4.4.1 Indexing

DLs contain a vast amount of data and information. Indexing mechanisms allow users to search the information space efficiently. Most DLs offer search services based on text indexing, which parses the sentences to build an index of words. Search engine technologies such as Lucene are widely used to repeatedly index and search through text files. Apache Solr, an open-source search platform, uses Lucene as its search engine and adds additional features including hit highlighting, faceted search, and dynamic clustering. Indexing of multimedia content such as images and video also is incorporated in some DLs (Wei 2002; Orio 2008) to allow content-based information retrieval.

18.4.4.2 User Needs

Societies, in general, and users, in particular, have need for information. Accordingly, DLs provide a range of services to help users satisfy their needs; key among those are the ones discussed in the following subsections.

18.4.4.2.1 Search

Searching is one of the most common activities of DL users. DLs offer a capability to search content at varied levels of object granularity. Generally, two types of searching can be supported: full-text search and metadata search. The searching process consists of two steps, sometimes integrated: retrieving and ranking. Supported by the indexing service (see Section 18.4.4.1), the retrieving step accesses the indexing data structure using the query terms entered by the user. Documents that (approximately) match the query terms are retrieved and given as output to the ranking process. The purpose of the ranking process is to find the best order of the documents for the user.

Faceted search is a powerful feature that provides a combination of searching and browsing (see subsequent sections), where the searching process is constrained using one or more of the attributes of the objects.

18.4.4.2.2 Browse

A browsing service provides another means for users to explore information in DLs. Browsing is based on the logical or physical organization of objects in the DL. Often, a rich organization like a hyperbase (resulting from linking texts or multimedia, as in hypertext and hypermedia) supports browsing, but simpler structures, like lists of dates or author names, also are widely used.

Browsing and searching can be considered as dual operations (Fox et al. 2012a). One can have the same results of searching using browsing and also the same results of browsing using searching. In the first case, query terms are used to determine the nodes in the navigation tree (graph) that

match them. The navigation path can be built by traversing the navigation tree backward from the matched nodes to the root of the tree. In the second case, one issues multiple queries that produce the same results as those from following the navigational path during browsing. Each query corresponds to one step in the navigational path that restricts more results than those of the previous query.

18.4.4.2.3 Visualize

Visualizing provides the DL users with the results of their requests, like searching and analyzing, through an interactive representation. The representation of the results depends on the kind of the operations producing the results, the context where the results are presented, and the type of data. Search results can be represented as a list or as a grid of items (Fox et al. 1993). Analysis results can be represented by graphs, charts, timelines, or maps.

18.4.4.2.4 Personalize

Personalization of information and services within a DL can be achieved in many different forms. Services can be personalized to meet the specific needs of a group or community of users. Notification, subscription, and tagging are some examples of personalized services for individual users. Along with services, information can be personalized based on user profile, interest, and activity within the DL (Neuhold et al. 2003), for example, in content recommender systems.

18.4.5 Integration

Within DLs, integration is required to bring people together and get coordinating processes to work. Content, storage structures, file formats, metadata schemas, policies, and software are often diverse within collaborations and federated systems. The integration of databases, content collections, and metadata structures remains a difficult task. One approach, used in DLs, involves accessing diverse underlying collections through Application Programming Interfaces (APIs) to conduct search over each system. DLs also provide a means of implementing a standard set of services and user interfaces that allow for integrated discovery and management in non-standardized collections. The goal of integration is to make the differences between systems, content, and services to appear seamless to end users, despite differences and conflicts in underlying components.

18.4.6 Interoperability

DLs can be considered to be information management systems that deal with different kinds of digital objects and provide different kinds of services that facilitate the manipulation of these objects and the extraction of information from them. Thus, there are many collections of objects in either digital form or real life that can be accessed from a DL through one interface. Accordingly, DLs should support interoperability, to overcome the differences and difficulties of interfacing such sources of information.

Collections of differing objects vary regarding organization (structure) and metadata. These syntactic-level differences sometimes aid when dealing with even more complicated semantic differences, which users expect will be addressed in a comprehensive interoperability solution. Two such types of interoperability that should be supported in DLs include data interoperability and services interoperability. Data interoperability focuses on providing access to different collections with different structures. One of the approaches developed for supporting data interoperability is through OAI (see Section 18.2.6.2).

18.4.7 Quality

DLs manage different types of objects and support services for different types of users. Assessing, evaluating, and improving the performance of a DL often is based on identifying the different concepts included in a DL and the dimensions of quality that are associated with these concepts. Table 18.1 shows

TABLE 18.1 Digital Library Concepts and Quality Dimensions

Digital Library Concept	Dimensions of Quality
Digital object	Accessibility
	Pertinence
	Preservability
	Relevance
	Similarity
	Significance
	Timeliness
Metadata specification	Accuracy
	Completeness
	Conformance
Collection	Completeness
	Impact factor
Catalog	Completeness
	Consistency
Repository	Completeness
	Consistency
Services	Composability
	Efficiency
	Effectiveness
	Extensibility
	Reusability
	Reliability

the main concepts that are needed to build a DL management system and what quality aspects we measure with respect to each concept. For example, for each digital object in the DL, we need to consider the relevance of the object to the user needs, whether the object can be preserved, how similar the object is to other objects, etc.

Information in DLs goes through several steps, starting from adding a raw digital object and ending by presenting the information to satisfy a user need, according to the "Information Life Cycle" (Borgman 1996). We can evaluate a DL by measuring the quality of information in each step of the information life cycle. Figure 18.3 shows the different steps included in the information life cycle in a DL, the services provided in each step, and the quality criteria that are used in evaluating those services.

Efficiency, effectiveness, completeness, relevance, compliance, timeliness, and similarity are examples of such evaluation criteria. For each criterion, one has to specify some measures (quality indicators). For example, efficiency of interactive services in a DL can be evaluated by measuring response time. Likewise, the relevance of the objects in the DL can be evaluated by measuring precision and recall.

18.5 Case Studies

There have been thousands of DLs used over the past decades, so understanding the DL field is aided by considering how the concepts explained earlier relate to a representative set of case studies.

18.5.1 ETANA

The ETANA-DL was built in support of Near Eastern archaeology (Shen et al. 2008). It involved collection of information from a number of archaeological sites, development of schema for each, mapping the schema into a global schema, harvesting metadata from sites using OAI-PMH, transforming that

metadata according to the schema mapping to be stored in a union metadata catalog, constructing an ontology for the domain with the aid of experts, and providing a broad range of services for archaeologists and others with interest. The browsing, searching, and visualizing were integrated, as was the whole system, based on the 5S framework, into a union DL.

18.5.2 AlgoViz

The AlgoViz project (AlgoViz 2011) is one of the primary content contributors to Ensemble. AlgoViz contains a catalog of visualizations that can be used to demonstrate various aspects of different algorithms. AlgoViz also has a bibliography collection related to algorithm visualizations (AVs) and hosts the field report collection—a forum like place where educators share their experience on using any particular AV. AlgoViz implements an OAI-PMH data provider service that maps catalog entry content to tags in the Dublin Core format. The metadata are thereby made available to Ensemble and other potential OAI service providers.

18.5.3 Ensemble

Ensemble (Ensemble 2009; Fox et al. 2010), the computing pathway project in the NSDL (see subsequent sections), is a distributed portal that collects and provides access to a wide range of computing education materials while preserving the original collections. It also hosts a community space to support groups of people with different interests related to computing education. Furthermore, there is a "Technologies" section that lists educational tools. Ensemble also shares key metadata with NSDL.

18.5.4 NSDL

The NSDL supports learning in Science, Technology, Engineering, and Mathematics (STEM) by providing access to a vast collection of related educational resources (NSDL 2001). Since 2000, the U.S. National Science Foundation has funded many groups in a variety of projects (e.g., Ensemble) to collect and manage quality metadata covering all key STEM areas (NSF 2012). NSDL uses harvesting and federated search, social networks, and a broad range of services, some centralized and some distributed, in one of the largest DL efforts yet undertaken.

18.5.5 CTRnet

The Crisis, Tragedy, and Recovery (CTR) network (CTRnet 2011) is a project aimed at building a human and digital network for collecting all information related to CTR events. A DL has been developed for managing the collected data and for providing services for communities that would help them in recovering from these events and for researchers to analyze data and extract useful information.

The CTRnet DL collects all types of data like reports, webpages, images, and videos. In collaboration with the Internet Archive (Internet_Archive 2000), many collections of websites have been prepared for further analysis and display to users. Integration with social media is also supported by collecting tweets related to CTR events. Tweet collections are analyzed for topic identification and opinion leader detection. The URLs in tweets are extracted, expanded, and stored for further use as seeds for archive building using local focused crawlers (around Heritrix) or the Internet Archive crawling service. The CTRnet DL provides communities and stakeholders with services like searching, browsing, visualizing, sharing, and analyzing data related to CTR events. Figure 18.4 shows key related data flows.

To aid in organizing the collected information, an ontology has been developed for the domain that includes all types of disasters and CTR events. The CTR ontology began as a merger of three disaster databases and is iteratively enhanced through the concepts extracted from collections archived and tweets collected using the yourTwapperKeeper (TwapperKeeper 2011) toolkit.

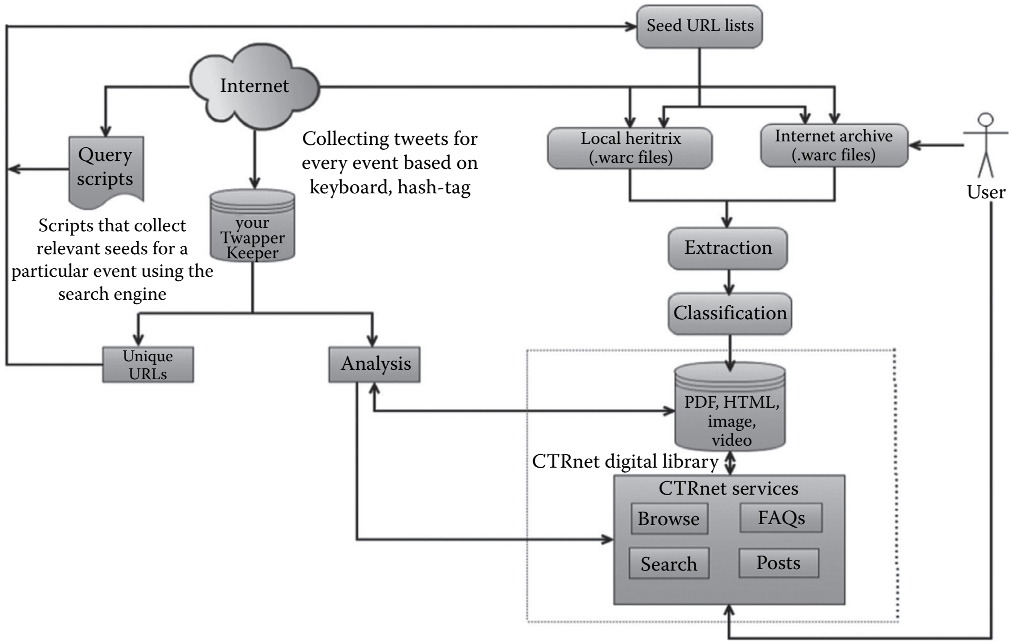

FIGURE 18.4 CTRnet data flow.

18.5.6 CINET

Educators teach about graphs and networks in multiple academic domains. In computer science, these topics are taught in courses on discrete structures. Graduate network science courses are based on this type of content, supporting education and research. These courses require real-world large graphs, scalable algorithms, and high-performance computing resources. CI including a portal has been developed to provide management for network science content and algorithms, including teaching advanced courses.

The CINET project provides educators, students, and researchers with access to a cloud computing cyber environment. This resource may be utilized to submit, retrieve, simulate, and visualize graph and network resources. It builds on our simulation-supporting digital library (SimDL) (Leidig 2012), which manages graphs, simulation datasets, large-scale analysis algorithms, results, and logging information.

Educators can use the DL as a repository for class projects, lecture materials, and research involving preexisting content and software. High-value educational content has been added to the repository; the DL includes the key datasets referred to in textbooks within this domain. Figure 18.5 details the system components in the CINET infrastructure. The DL provides core services to store and retrieve network graphs and algorithms. It also provides higher level services related to user interfaces, simulation applications, and computing resources.

This class of DLs provides services not commonly found in full-text collections. Thus, the DL automatically processes computer-generated content, extracts metadata from files, builds indexes of distributed scientific content, and provides search over highly structured numeric files. Infrastructure independent communication brokers are used to send and receive data in the DL and invoke DL services through automated workflow processes. This architectural design allows for generated scientific information to be captured, indexed, managed, curated, and accessed without human intervention. Management of scientific content in this manner provides a standardized management system for later efforts to support interoperability within a domain. Additional simulation-specific services aim to support advanced scientific workflow functions. These services include incentivizing researchers to contribute content, memorizing (i.e., caching) and reusing existing results, scientific workflow provenance

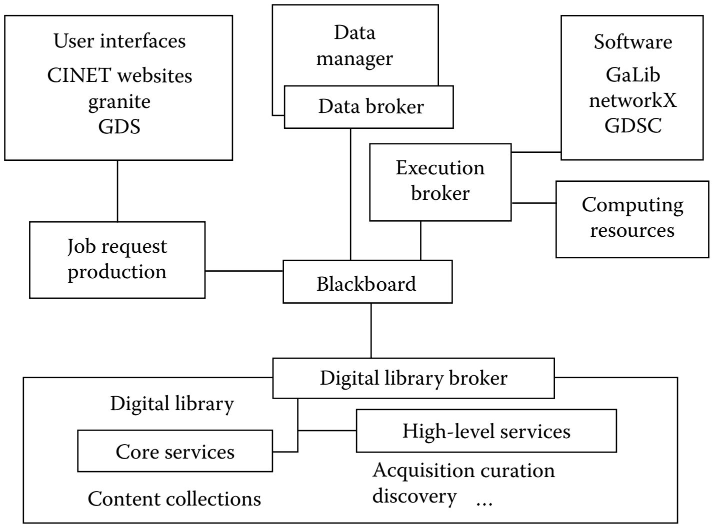

FIGURE 18.5 CINET system components.

tracking, curating of large-scale content, and scientific document searching. SimDL and its related services represent an emerging class of DLs applied in the sciences.

18.5.7 Publisher DLs

By the late 1980s, it was becoming clear that academic, professional, and commercial publishers were in the midst of an electronic revolution that would directly affect their activities (Fox 1988). This has led to the adoption of DL technologies to cover much of the publishing world. Automated systems are commonly used to receive submissions, handle reviewing, manage editorial work, collect final versions of documents, archive publications, and provide access (often through subscription or per-item payment schemes) (ACM 2000; IEEE-CS 2004).

18.5.8 WDL

The World Digital Library (WDL 2012) aims to promote international understanding and cross-cultural awareness by providing free multilingual access to online metadata and images of cultural riches of United Nations for Education, Science and Culture Organization (UNESCO) member states and others that have become partners. The types of items include books, journals, manuscripts, maps, motion pictures, newspapers, prints/photographs, and sound recordings.

In June 2005, Dr. James H. Billington, U.S. Librarian of Congress, proposed the establishment of the WDL to UNESCO. In December 2006, key stakeholders from around the world attended an Experts Meeting sponsored by UNESCO and the Library of Congress, deciding to establish working groups focused on standards and content selection. By October 2007, a prototype of WDL was presented at the UNESCO General Conference. In April 2009, WDL was officially launched and opened to the public. WDL has an emphasis on quality, with quantity also desired but not at the expense of quality. Regarding the development of WDL, some of the key features and aspects are as follows:

1. Metadata: Each item in WDL is described, indicating its significance as well as what it is. Curators and experts provide context to stimulate the curiosity of students and public interest in cultural heritage. There is consistent coverage of topical (based on the Dewey Decimal System), geographical, and temporal information.

2. Languages: Access to metadata, navigational aids, and supporting content like curator videos is enabled for seven languages: Arabic, Chinese, English, French, Portuguese, Russian, and Spanish.
3. Collaborative networks: Technical and programmatic networks connect partners, stakeholders, and users—all in a spirit of openness. There are contributions, including from libraries and archives, of: content collections, technology, finances, and involvement in working groups.
4. Digitization: The Library of Congress and partners in Brazil, Egypt, Iraq, and Russia have digital conversion centers to produce high-quality digital images, as can be found in the WDL. WDL intends to work with UNESCO to encourage the establishment of additional digital conversion centers around the world.

18.6 Future

The DL field—and its "children" like repositories, CMSs, and web portals—will continue to have broad impact as people around the globe utilize specialized systems to work with particular types of content, providing tailored assistance that goes beyond the general services of search engines. Supporting research and development efforts will continue, sometimes referred to using "DLs," but also carried out by those whose first loyalty is database processing, information retrieval, knowledge management, human–computer interaction, hypertext, electronic publishing, or other related domains. DLs are the result of synergies informed by all these fields, so conceptual and practical integration and interoperability is perhaps the most important type of DL research required. Establishing a firm formal foundation, supporting transparency across data/information/knowledge collections, developing consensus regarding quality measures and indicators, and shifting toward modular Semantic Web–oriented implementations atop a service-oriented architecture, are among the key challenges now faced. Funding and collaboration are required to address these and other problems explained earlier, so users working in a particular domain can benefit from improved services (e.g., support for collection security, integrated text and data analysis workflows, and enhanced information visualization). The discussion earlier should help you understand this important area, so you can more effectively use DLs and/or can assist in their further unfolding.

Knowledge Discovery and Data Mining

Jennifer Jie Xu
Bentley University

19.1 Introduction

In today's information age, the competitive advantage of an organization no longer depends on their information storage and processing capabilities (Carr 2003) but on their ability to analyze information and discover and manage valuable knowledge. Knowledge discovery and data mining, which is often referred to as *knowledge discovery from data* (KDD), is a multidisciplinary field bringing together several disciplines, including computer science, information systems, mathematics, and statistics (Han et al. 2011). The field emerged in response to the demand for knowledge management and decision support based on large volumes of data in business, medicine, sciences, engineering, and many other domains. Since the first KDD conference in 1989 (Fayyad et al. 1996b), KDD research has made significant progress and had a far-reaching impact on many aspects in our lives.

The primary goal of knowledge discovery and data mining is to identify "valid, novel, potentially useful, and ultimately understandable patterns in data" (Fayyad et al. 1996c, p. 30). Huge amounts of data are gathered daily and stored in large-scale databases and data warehouses: sales transactions, flight schedules, patient medical records, news articles, financial reports, blogs, and instant messages, among many others. Valuable knowledge can be extracted from these data to generate important intelligence for various purposes. For example, credit card companies can analyze their customers' credit card transaction records and profile each customer's purchasing patterns (e.g., the average spending amount, the average monthly balance, and the time and locations of regular purchases). Such knowledge can, for example, be used to detect credit card fraud when some unusual, suspicious transactions occur (e.g., unusually high spending amount) (Bhattacharyya et al. 2011).

Many KDD techniques have been developed and applied to a wide range of domains (e.g., business, finance, and telecommunication). However, KDD still faces several fundamental challenges, such as

- *Data volume*: Because of the rapid advances in information technology, the volumes of data that can be used for knowledge discovery purposes grow exponentially: companies collect transactional data in their daily business, research institutions and laboratories record and make available results from their scientific experiments, and healthcare providers and hospitals monitor patients' health conditions and changes. Therefore, the KDD techniques must be sufficiently efficient and scalable to handle large volumes of data in a timely manner. Especially for real-time applications such as computer network intrusion detection, the KDD technology must be quick enough to detect and respond to any intrusion to prevent it from causing devastating damages to computer systems and networks (Ryan et al. 1998).
- *Data types and formats*: Data can be of many different types and formats: numerical, text, multimedia, temporal, spatial, and object-oriented. Numerical data (e.g., product price, order total, blood pressure, and weather temperature) are also called structured data and can be organized easily using relational databases. Other types of data are often called unstructured data because they may contain text and other data types that do not fit in some predefined data models. Because of the variety and complexity in data types and formats, the KDD techniques must be able to handle the specific characteristics of a data type. For example, text mining techniques must be able to recognize terms and phrases in free-text documents, parse sentences into syntactical components, and extract meaningful syntactical and semantic patterns from texts (Feldman and Sanger 2006).
- *Data dynamics*: In many applications, the data are constantly changing. For example, in traffic monitoring and control systems, the data collected using video cameras and sensors installed along streets are in the form of continuous sequences of digitalized signals. This poses a significant challenge on the storage and processing power of the systems.
- *Data quality*: The quality of data can substantially affect the quality and value of the patterns extracted from the data. When the data contain many errors, noise, and missing values, the extracted patterns based on such data may be inaccurate, incorrect, misleading, or useless. Therefore, the KDD techniques must be robust enough to handle low-quality data to ensure the quality of the results.

The KDD community has kept developing innovative techniques and methods to address these challenges. This chapter will provide an overview of the principles, techniques, applications, and practical impacts of KDD research. The next section will introduce the KDD process and the underlying principles for major data mining techniques. We will then review the applications and impacts of KDD technologies. The research issues and trends of future KDD research will be discussed. The last section will summarize this chapter.

19.2 KDD Principles and Techniques

As introduced earlier, KDD is a multidisciplinary field, which is related to several different research areas and fields—statistics, machine learning, artificial intelligence, neural networks, databases, information retrieval, and linguistics—which all have contributed to the development and evolution of the KDD field. There have been several views regarding the fundamental principles of KDD: data reduction view, data compression view, probabilistic view, microeconomic view, and inductive database view (Mannila 2000).

The data reduction view treats KDD as a process to reduce the data representation. In the data compression view, KDD is a way to compress given data into certain patterns or rules. The probabilistic view regards KDD as a statistic problem and the extracted knowledge as hypotheses about the data (Mannila 2000). The microeconomic view considers KDD as a problem-solving process intended to find useful

knowledge to support decision making (Kleinberg et al. 1998). The inductive database view assumes that the patterns are already embedded in the data and the task of KDD is to query the database and find the existing patterns (Imielinski and Mannila 1996).

These views and theories have together built the foundation of the KDD field. In reality, knowledge discovery is not a simple, one-step task but a complex process involving multiple stages and activities. With different contexts, goals, applications, and techniques, the underlying principles may not be the same.

19.2.1 KDD Process

Although many people use "knowledge discovery" and "data mining" interchangeably, the two terms actually refer to different things. More specifically, data mining is a core step in the multistage process of knowledge discovery (Han et al. 2011). Figure 19.1 presents an overview of a typical knowledge discovery process:

- *Cleaning and integration*: This preprocessing step includes such operations as removing noise, correcting errors, resolving inconsistencies, handling missing and unknown values, and consolidating data from multiple sources. For example, when mining sales data, abandoned or invalid transactions can be removed from the dataset. This step is critical to ensure that the preprocessed data meet the quality requirements for the later steps in the process.
- *Selection and transformation*: Sometimes the original dataset contains features (or fields and attributes in database terms) that are not relevant to a particular KDD application or task. By selecting only relevant features, the number of variables under investigation can be reduced and the efficiency of the KDD process can be improved. In addition, the original data may need to be transformed, summarized, or aggregated before they can be used for pattern extraction. For example, in social network mining applications, the data about social relationships between people may not be directly available but have to be inferred from other types of data such as group membership (Chau and Xu 2007) and paper coauthorship (Newman 2004a).
- *Data mining*: This is the most important step in the entire KDD process. In this step, effective and efficient algorithms, methods, and techniques are applied to the data to extract patterns, rules, or models. We will discuss this step in greater detail in the following sections.

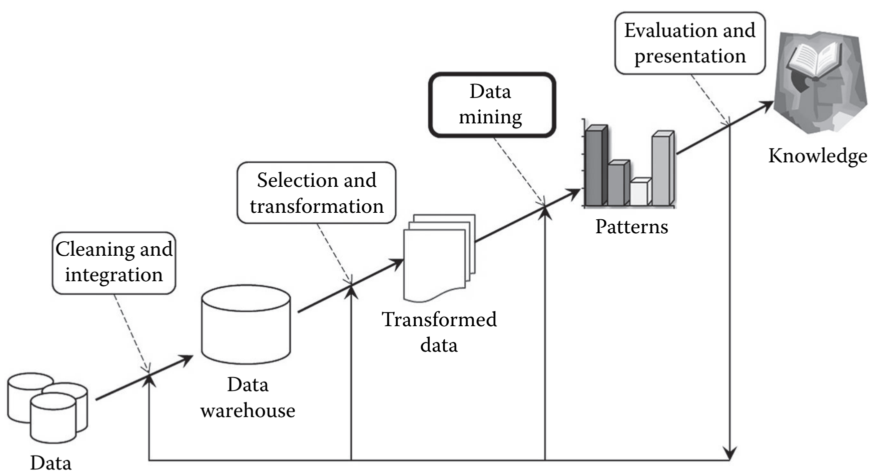

FIGURE 19.1 Overview of the KDD process. (Adapted from Han J. et al., *Data Mining: Concepts and Techniques*, 3 edn., Morgan Kaufmann, Amsterdam, the Netherlands, 2011.)

- *Evaluation and presentation*: The patterns extracted from the data must be subject to evaluation (e.g., by domain experts) to determine its quality, validity, interestingness, and value. Patterns that are trivial or not useful for the particular application will not be considered knowledge. Finally, the valid, novel patterns extracted from the data must be presented in a way that they can be interpreted and understood relatively easily by users or decision makers because the ultimate goal of KDD is to provide "actionable" knowledge that supports decision making (Han et al. 2011). Various presentation and visualization techniques may be used in this step to accomplish this goal.

Because data mining is the key step in the KDD process, we will focus in the following sections on data mining techniques, applications, and impacts. Depending on the goals of KDD tasks, traditional data mining techniques can be categorized into four types: *association mining*, *classification and prediction*, *clustering,* and *outlier analysis*. We will discuss the basic principles for major algorithms and methods of these types in this section. We will also briefly introduce a few relatively new mining types including text mining, web mining, and network mining.

19.2.2 Association Mining

Association mining identifies frequently occurring relationships among items in a dataset (Agrawal et al. 1993). A widely used example of association mining is the market basket analysis, which is intended to find items that customers often purchase together. For example, a market basket analysis on customer grocery shopping transactions may reveal that when customers buy hot dogs, very likely they will also buy buns to go with the hot dogs. Such findings may help stores better design the floor layout and plan the shelf space (e.g., placing buns close to hot dogs) so as to encourage sales of both items. Market basket analysis has also been used in online stores. The online retailer, Amazon.com, has long been using customers' "co-purchasing" information to promote sales of related items.

An association relationship is often represented as a rule, $X \Rightarrow Y$, where X and Y are two itemsets, to indicate that itemset X and itemset Y are associated. Moreover, the rule implies that the occurrence of X will lead to the occurrence of Y. Note that the reverse of this rule may not necessarily be true. In the aforementioned example about hot dogs and buns, the rule can be represented as {Hot dog} ⇒ {Bun}, which means that customers who buy hot dogs will also buy buns. An itemset consisting of k items is called a k-itemset. In this example, both {Hot dog} and {Bun} are 1-itemsets.

It can be imagined that a huge number of association rules can be mined out of a transactional dataset. However, not all the association rules are necessarily useful. Some associations may occur frequently, while others occur only a few times. To evaluate the "strength" of an association rule, two measures have been used to filter out weak associations: *support* and *confidence*. An itemset is *frequent* if it satisfies a predefined minimum support. Only associations that meet both the predefined minimum support and minimum confidence requirements will be considered strong, useful rules.

Support and confidence are defined in the form of probability:

$$\text{Support}(X \Rightarrow Y) = P(X \cup Y),$$

$$\text{Confidence}(X \Rightarrow Y) = P(Y \mid X).$$

For example, suppose 100 customer transactions are evaluated and it is found that 40 customers purchased hot dogs, 50 customers purchased buns, and 30 customers bought both hot dogs and buns. Using the two formulas, we get that Support = 30% and Confidence = 75%. Therefore, the complete rule will be represented as:

$$\{\text{Hotdog}\} \Rightarrow \{\text{Bun}\}\ [\text{Support} = 30\%, \text{Confidence} = 75\%].$$

This means that this association rule is supported by 30% of the transactions under consideration (i.e., hot dogs and buns co-occur in 30% of the transactions), and 75% of the customers who purchased hot dogs also purchased buns.

Researchers have proposed many methods and algorithms for finding association rules in databases. Among these methods, the Apriori algorithm (Agrawal and Srikant 1994) is the most widely used. The fundamental principle on which this algorithm is based is that there exists the prior knowledge of the property of a frequent itemset: all nonempty subsets of a frequent itemset must also be frequent. This property is used to search from data for all frequent itemsets, which have at least the minimum support. The frequent itemsets are then further examined to find strong association rules that also have minimum confidence.

The search for frequent itemsets is a progressive, iterative process in which the frequent k-itemsets are found using (k − 1)-itemsets. The algorithm has two steps in each iteration: joining and pruning. The algorithm starts with the initial scan of the dataset and finds the set S_1, which contains all 1-itemsets that meet the minimum support requirement. S_1 will be joined with itself to find the candidate set, S_2, for frequent 2-itemsets. Based on the prior knowledge about the property of frequent itemsets, all nonfrequent subsets of S_2 (i.e., the subsets are not contained in S_1) will be removed from S_2 in the pruning step. These two steps are repeated for each k until no frequent itemset can be found for k + 1.

After all the frequent itemsets are identified, association rules can be generated by finding the subsets of each itemset and calculate their confidences. Rules that do not satisfy the minimum confidence will be discarded. The output is a number of strong association rules.

The Apriori algorithm is intuitive and easy to implement. However, as the data volume increases, it becomes quite slow because it requires scanning the dataset repeatedly. Many variations of the algorithm have been proposed to increase the efficiency and scalability to handle large volumes of data, including the hash-based methods (Park et al. 1995), transaction reduction, partitioning (Savasere et al. 1995), and sampling (Toivonen 1996). An approach called frequent pattern growth (FP-Growth) that compresses the original dataset to avoid time-consuming candidate itemset generation has also been proposed (Han et al. 2000). All these new techniques have improved the performance of association rule mining in large databases.

19.2.3 Classification and Prediction

Classification is a type of data mining technology used to map records into one of several predefined categories based on attribute values of the records. For example, attributes in a patient's medical records such as his/her blood sugar level, age, weight, and family medical history can be used to predict the patient's risk level of having diabetes in the future (low vs. high) (Prather et al. 1997).

Classification is closely related to machine learning, pattern recognition, and statistics (Han et al. 2011). It usually consists of a training step and a testing step. During the training step, a classification algorithm reads records with their known category labels and generates a classification model (i.e., the classifier) based on the training data. In the testing step, the known category labels of the testing records are removed and the algorithm will predict the labels based on the learned model. These classifier-assigned labels are then compared against the known labels of the testing records to determine the performance of the classification. If the performance exceeds a predefined threshold, the algorithm, together with the learned model, can then be used to classify new data whose category labels are unknown. Because classification involves the training step in which the category labels are given, classification is also called supervised learning. Examples of classification applications include fraud detection (Bhattacharyya et al. 2011), computer and network intrusion detection (Ryan et al. 1998), corporate failure prediction (Eksi 2011), and image categorization (Zaiane et al. 2001).

Classifiers are used to generate discrete-valued category labels (e.g., low risk vs. high risk, success vs. failure). For applications dealing with continuous variables (e.g., yearly revenue), a traditional statistical method, regression analysis, can be used. Because regression analysis has long been studied and used

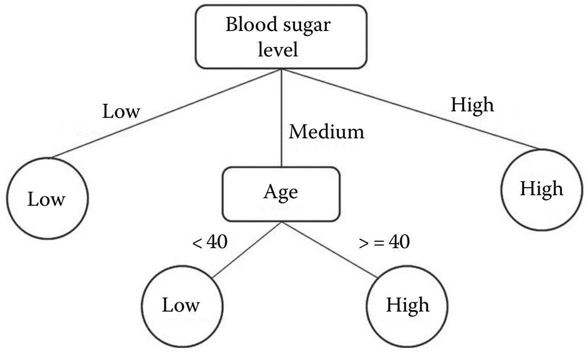

FIGURE 19.2 An example of a decision tree.

in statistics and many textbooks and literature that introduce and explain regression analysis can be found, we focus in this chapter on classifiers.

The model generated by a classifier can be represented as decision rules (if-then statements), decision trees, mathematical formulas, or neural networks. In a decision tree, for example, each internal node represents a test on the value of an attribute, each branch specifies an outcome from the test, and each leaf node corresponds to a category label. Figure 19.2 presents an example of a hypothetical decision tree for predicting the risk level (low vs. high) of diabetes for patients.

There have been many classification techniques including induction decision tree-based methods (Breiman et al. 1984; Quinlan 1986, 1993), naïve Bayesian classifiers (Weiss and Kulikowski 1991), Bayesian belief networks (Heckerman 1996), neural networks (Rumelhart and McClelland 1986), support vector machines (SVM) (Burges 1998; Vapnik 1998), and genetic algorithms (Goldberg 1989), among many others. Different classification methods are based on different principles. We briefly introduce a few methods as follows.

Decision tree induction methods such as ID3 (Quinlan 1986), C4.5 (Quinlan 1993), and classification and regression trees (CART) (Breiman et al. 1984) are based on the principle of *information entropy* in information theory (Shannon 1951). Information entropy generally measures the uncertainty and randomness in the "information content" of messages. The higher the uncertainty is, the higher the information entropy is. These classification methods take a divide-and-conquer strategy. The process begins with the entire set of attributes, and the attribute set is recursively partitioned into smaller subsets while the decision tree is built. The attribute that can reduce the information entropy the most will be selected as the splitting attribute for a partition. Each partition corresponds to an internal node of the decision tree.

The underlying principle of naïve Bayesian classification is Bayes' theorem of posterior probability, along with the assumption that the effects of different attributes on the categories are independent of each other (Weiss and Kulikowski 1991). Based on this theorem, the posterior probability, $P(C_i|R)$, for a record R belonging to a category C_i given the attribute values of R, can be calculated using the posterior probability $P(R|C_i)$ and prior probabilities $P(R)$ and $P(C_i)$:

$$P(C_i|R) = P(R|C_i)P(C_i)/P(R).$$

The record R is assigned to a specific category C_i if $P(C_i|R) > P(C_j|R)$, for all $j \neq i$.

Neural network classifiers learn a classification model by simulating the ways in which neurons process information (Rumelhart and McClelland 1986). A neural network usually consists of several layers of nodes (neurons). The nodes at the first layer (the input layer) correspond to the record attributes and the nodes at the last layer (the output layer) correspond to the categories with associated labels. There may be one or more layers between the first and the last layer. The nodes at a layer are connected with nodes at the adjacent layers and each connection has an associated weight. During the training step,

the network receives the values of the attributes from the input layer. In order to generate the category labels that match the given labels at the output layer, the network dynamically adjusts the weights of the connections between layers of nodes. During the testing step, the learned weights are used to predict the labels of testing records. The biggest disadvantage of neural networks is that the learned classification model is hard to interpret because it is encoded in the weights of the connections.

Genetic algorithms incorporate the principles of natural evolution by imitating the genetic crossover and mutation operations during reproduction processes of living beings (Bäck 1996). The training stage involves multiple iterations. The initial set of decision rules, which are represented by strings of bits, are randomly generated. In each iteration, the rules are updated by swapping segments of the strings (crossover) and inverting randomly selected bits (mutation). The fitness of rules, which is usually measured by accuracy, is assessed in each iteration. The process stops when all rules' fitness scores exceed a predefined threshold.

The performance of a classification method can be measured by efficiency and effectiveness (accuracy, precision, and recall) in general. Studies have shown that decision tree induction methods are quite accurate but slow, limiting their applicability to large datasets. The naïve Bayesian classifiers are comparable to decision tree induction methods in effectiveness. Both neural networks and genetic algorithms can achieve high effectiveness in some domains but often require long training time (Han et al. 2011).

19.2.4 Clustering

Clustering is used to group similar data items into clusters without the prior knowledge of their category labels (Jain et al. 1999). In this sense, clustering is a type of exploratory, unsupervised learning. The basic principle of clustering is to maximize within-group similarity while minimizing between-group similarity (Jain et al. 1999). Figure 19.3a presents an example of clustering analysis. Except for the two data points p and q, all points fall into either one of the clusters represented by the dashed circles. Points within a circle are closer to each other than to points in the other circle. Clustering has been used in a variety of applications including image segmentation (Jain and Flynn 1996), gene clustering (Getz et al. 2000), and document categorization (Roussinov and Chen 1999).

Two types of clustering methods have been widely used: hierarchical and partitional. Hierarchical methods group data items into a series of nested clusters, forming a hierarchy of partitions. Partitional methods, in contrast, generate only one partition of the entire dataset.

Hierarchical methods are further categorized into agglomerative and divisive methods. Agglomerative methods such as variations of the single-link algorithm (Sibson 1973) and complete-link algorithm (Defays 1977) take a bottom-up approach and grow the clusters progressively. At the beginning, each data item is treated as a cluster. Using distance as the measure for the similarity (or dissimilarity) between data items, the two closest data items are merged into a new cluster and the distances between this new cluster and other clusters are updated. The algorithm then searches for another pair of clusters

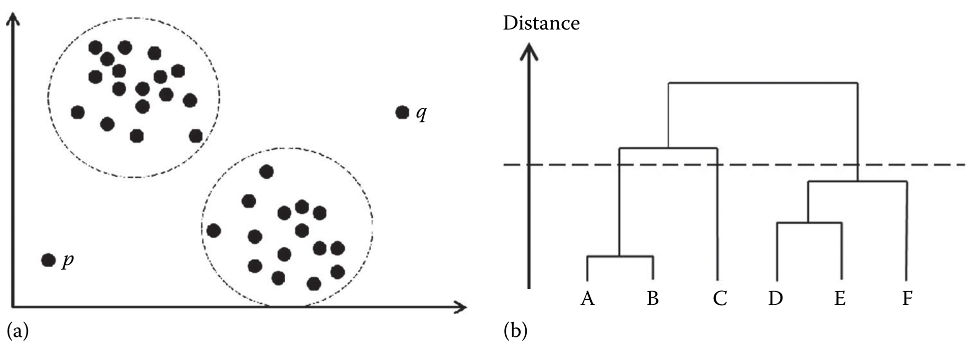

FIGURE 19.3 (a) An example of a clustering analysis and (b) an example of a dendrogram.

whose distance is the smallest among all between-cluster distances and merges them together. This process is repeated until all clusters are merged into a single cluster. Divisive methods reverse the clustering process of agglomerative methods by taking a top-down approach. The initial cluster includes all data items and the algorithms progressively split the clusters into smaller ones.

The pattern (i.e., nested partitions) generated by hierarchical methods is represented as a dendrogram in which each distance level corresponds to a merger of two clusters. The dendrogram can be cut at any level to generate a particular partition of the dataset. Figure 19.3b presents an example of a dendrogram.

Partitional clustering methods require the prior knowledge of the number of clusters, *k*. A partitional algorithm groups the data items into *k* clusters by maximizing an objective function. The most commonly known partitional method is the *k*-means algorithm (Lloyd 1957). At the beginning, the algorithm randomly selects *k* data items and treats them as the centers of the *k* clusters. The remaining items are then assigned to their closest clusters. The new center of each cluster is recalculated after receiving new items. All the data items are then reassigned to clusters based on the updated centers. The process terminates if the cluster centers do not change. Because *k*-means algorithms often terminate at the local optimum, they may need to be run several times to find the global optimum.

Both hierarchical and partitional methods have their advantages and disadvantages. The number of clusters does not need to be prespecified for hierarchical methods. However, it is often difficult to determine the level at which the dendrogram should be cut to yield a meaningful partition. Partitional methods require the prior knowledge regarding the number of clusters but can generate the desired partition of the data (Jain and Dubes 1988). In terms of efficiency and scalability, partitional methods are faster and more scalable for large datasets than hierarchical methods are.

Other types of clustering techniques have also been developed. For example, density-based methods can be used to cluster spatial data (Ester et al. 1996). Self-organizing map (SOM) (Kohonen 1995), which is a neural network-based clustering technique, can be used to directly distribute multidimensional data items into regions (clusters) in a two-dimensional space (Chen et al. 1996). In network data mining applications, various clustering methods have been proposed for detecting communities, which can be viewed as densely knit clusters of nodes in networks. For instance, Girvan and Newman (2002) proposed a divisive algorithm that progressively removes links to break a connected network into communities. However, the algorithm is rather slow. A few alternative methods, such as the modularity-based algorithm (Clauset et al. 2004), have been proposed to provide better efficiency.

19.2.5 Outlier Analysis

Most data mining tasks, such as association mining, classification, and clustering, are intended to search for commonality among data and to seek patterns that occur frequently, regularly, or repeatedly. Outliers, which deviate substantially from the rest of the data items, are often treated as noise and removed from the data during the cleaning stage in a KDD process. For example, in Figure 19.3a, points *p* and *q* are outliers. They clearly do not belong to either cluster and may be ignored or removed in clustering applications. However, in some situations, outliers that represent unusual or abnormal behaviors must be identified. Credit card fraud detection, for instance, is looking for abnormal transactions that do not fall into the range of normal transactions or are significantly different from the regular purchasing patterns of credit card owners.

Unlike other data mining types such as classification and clustering, in which the development of the mining algorithms may not have to depend on the characteristics of specific applications, outlier detection is largely application dependent. For different applications in different domains, the definitions for outliers and the detection methods may be drastically different. As a result, no dominating methods have emerged to be used to detect outliers in most applications. Basically, depending on the goals and requirements of a specific application, classification and clustering methods may be used to detect outliers (Han et al. 2011).

For example, if the data sample contains records that are labeled by domain experts as outliers, classification methods can be used to detect future outliers that are similar to the known ones. For data without category labels, unsupervised methods such as clustering algorithms can be used to identify data items that are exceptionally dissimilar with the rest of the data.

In addition, statistical approaches have also been proposed for outlier detection in situations where the "normal behavior" of the data is known (Abraham and Box 1979; Agarwal 2006). Such approach is under the assumption that the normally behaved data are all generated by the same stochastic mechanism and outliers are those generated by different mechanisms form the rest of the data.

19.2.6 Other Data Mining Types

In addition to the four types of traditional data mining, there have been several new types of data mining including text mining, web mining, network mining, spatiotemporal data mining, stream data mining, and visual data mining, among many others. We briefly introduce the first three types here:

1. *Text mining*: Text mining has been employed in a wide range of applications such as text summarization (Fattah and Ren 2009), text categorization (Xue and Zhou 2009), named entity extraction (Schone et al. 2011), and opinion and sentiment analysis (Pang and Lee 2007). Text mining is closely related to computational linguistics, natural language processing, information retrieval, machine learning, and statistics (Feldman and Sanger 2006). Text mining requires a great deal of preprocessing in which the text (e.g., news articles) must be decomposed (parsed) into smaller syntactical units (e.g., terms and phrases). Sometimes, the text data may also need to be transformed into other types. For example, in some text mining applications, terms extracted from the documents in the entire corpus are treated as features and documents are treated as records. Thus, each document can be represented as a Boolean vector in which a true (or false) value for a feature indicates the presence (or absence) of the corresponding term in the document. During the mining stage, depending on the requirements of the specific applications, various data mining methods such as association mining, classification, and clustering may be used to find patterns in the text. For example, classification and clustering are frequently used in text categorization applications (Feldman and Sanger 2006).
2. *Web mining*: The web has provided a vast amount of publicly accessible information that could be useful for knowledge discovery. Web mining techniques can be categorized into three types (Kosala and Blockeel 2000): content mining, structure mining, and usage mining. Web content mining extracts useful information from the text, images, audios, and videos contained in web pages (Zamir and Etzioni 1998; Pollach et al. 2006). Web structure mining examines hyperlink structures of the web. It usually involves the analysis of in-links and out-links of a web page and has been used for search engine result ranking and other web applications (Brin and Page 1998; Kleinberg 1999). Web usage mining analyzes search logs or other activity logs to find patterns of users' navigation behavior or to learn user profiles (Srivastava et al. 2000; Nasraoui et al. 2008; Malik and Rizvi 2011).
3. *Network mining*: Unlike traditional data mining that extracts patterns based on individual data items, network mining is used to mine patterns based on the relationships between data items. Network mining is grounded on three theoretical foundations: graph theory from mathematics and computer science (Bollobás 1998), social network analysis from sociology (Wasserman and Faust 1994), and topological analysis from statistical physics (Albert and Barabási 2002). Network mining is intended to find various structural patterns, such as structural positions that have special roles (e.g., leaders, gatekeepers) (Freeman 1979), communities (Clauset et al. 2004; Newman 2004b; Bagrow 2008), and future links (Liben-Nowell and Kleinberg 2007). The techniques include descriptive measures (e.g., centrality measures, network diameters), statistical approaches (e.g., degree distributions), and clustering analysis (e.g., modularity-based algorithms), among many others. Network mining is a young, fast-growing area and has great potential for various applications.

19.3 KDD Applications and Impacts

KDD technologies have made huge impact on every aspect of our lives whether we realize it or not. When we go to a retail store to shop, for example, we may be able to find related items easily on the shelves due to the store's effective use of the results from market basket analyses. When we search for information using a search engine (e.g., Google), by entering just a few query terms, we can find the information we need on the web pages returned by the search engine based on web content and structure mining results. Many credit card companies and banks constantly watch for suspicious, fraudulent transactions to protect us from identify theft crimes. These benefits and the associated convenience have been provided by advanced technologies developed in the KDD research.

The KDD research, to a large extent, is application-driven. Many new methods and techniques are developed in response to the demand for knowledge discovery applications in various domains. In this section, we review a few examples of the domains in which KDD technologies have made significant impacts.

19.3.1 Finance

KDD technologies have long been used in the financial industry to support decision making in various applications including fraud detection, stock market forecasting, corporate distress and bankruptcy prediction, portfolio management, and financial crime (e.g., money laundering) investigation (Zhang and Zhou 2004; Kovalerchuk and Vityaev 2010). In these applications, multiple types of data mining methods often are combined and integrated to achieve high performance, quality, and interpretability of the results:

- *Fraud detection*: Fraud detection is used to identify fraudulent transactions, behaviors, and activities that deviate from the regular patterns of behavior. Phua et al. (2010) categorized frauds into four types: internal frauds (e.g., fraudulent financial reporting) (Kirkos et al. 2007; Glancy and Yadav 2011; Ravisankar et al. 2011), insurance frauds (Bentley 2000; Viaene et al. 2004), credit transaction frauds, and telecommunication frauds (Alves et al. 2006). In the financial context, the most frequently studied type is credit card fraud detection. Because fraudulent transactions are usually outliers that occur infrequently and irregularly, classification-based outlier analysis is often employed in such applications. For example, Paasch (2007) used neural networks together with genetic algorithms to detect fraudulent credit card transactions in a real dataset that contained 13 month's worth of 50 million credit card transactions. Using the same dataset, Bhattacharyya et al. (2011) combined SVM and logistic regression models for fraud detection. Many other data mining methods have also been used in credit card fraud detection such as Bayesian classifiers (Panigrahi et al. 2009), hidden Markov models (Srivastava et al. 2008), and association rules (Sánchez et al. 2009).
- *Stock market forecasting*: Stock market forecasting attempts to predict the future prices or returns of stocks or other securities such as bonds. The input data usually are time-series data (e.g., stock prices) that are measured at successive time points at equal time intervals. There have been a large number of studies on stock market forecasting using neural network-based methods (Trippi and Desieno 1992; Grudnitski and Osburn 1993; Wood and Dasgupta 1996; Wong and Selvi 1998). Neural networks have been also integrated with other methods to generate better prediction accuracy. For example, Hadavandi et al. (2010) proposed to integrate genetic fuzzy systems and artificial neural networks to build a stock price forecasting expert system. This approach has been tested and used in the prediction of the stock prices of companies in the IT and airline sectors.
- *Corporate distress and bankruptcy prediction*: Firms and corporations may face difficult economic and financial conditions. Financial distress sometimes may lead to bankruptcy. Accurate and timely prediction of financial distress and bankruptcy can help the important stakeholders of

the firms take appropriate strategies to reduce or avoid possible financial losses. Chen and Du (2009) proposed to use neural networks to construct a distress model based on several financial ratios. Similarly, neural network-based techniques are used in other studies to predict financial distresses facing firms and corporations (Coats and Fant 1991–1992, 1993; Altman et al. 1994). The prediction of bankruptcy is also formulated as a classification problem using various features. In addition to the classic bankruptcy prediction model, the Z-score model, which is based on discriminant analysis* (Altman 1968), a variety of classification methods have been used including genetic algorithms (Shin 2002), neural networks (Fletcher and Goss 1993; Zhang et al. 1999), logistic regression and discriminant analysis (Back et al. 1996), and the hybrid approach combining several classifiers (Lee et al. 1996). Sung et al. (1999) distinguished crisis economic conditions from normal conditions under which a firm is facing the possibility of bankruptcy. The interpretive classification model they used identified different factors that should be used to predict bankruptcy under different conditions.

19.3.2 Business and Marketing

Business is a well-fit domain for knowledge discovery and data mining. Companies around the world are capturing large volumes of data about their customers, sales, transactions, goods transportation and delivery, and customer reviews of products and services. Using these data, KDD technologies have been playing a critical role in supporting various business functions such as customer relationship management (CRM), customer profiling, marketing, supply chain management, inventory control, demand forecasting, and product and service recommendation (Ghani and Soares 2006):

- *CRM and customer profiling*: CRM is aimed at helping businesses understand and profile the needs and preferences of individual customers and manage the interaction and relationships with their customers. As a business expands and the size of its customer base increases, it becomes increasingly difficult to learn customer profiles using manual approaches. Data mining technologies provide a great opportunity to serve the purposes of CRM in terms of customer identification, attraction, retention, and development (Ngai et al. 2009; Chopra et al. 2011). Customer profiles may include not only the demographics of the customers but also their purchasing history and patterns such as frequency and size of purchases and customer lifetime values (Shaw et al. 2001). Association mining-based market basket analysis, as reviewed in the previous section, can provide a collection of frequent itemsets and association rules that represent such patterns. In addition, neural networks, decision trees, and clustering are also widely used in CRM (Ngai et al. 2009). For example, neural networks and genetic algorithms were combined for customer targeting (Kim and Street 2004), a Bayesian network classifier was used to model the changes in the customer lifecycles (Baesens et al. 2004), multiple classifiers were integrated to predict customer purchasing patterns (Kim et al. 2003), and k-means algorithms were used to identify groups of customers motivated by the importance of stores in shopping centers (Dennis et al. 2001).
- *Direct marketing and viral marketing*: As today's markets become more competitive and fast changing, mass marketing, which relies on mass media such as newspaper, television, and radio to advertise products and services to the general public, becomes less effective. In contrast, direct marketing selects and targets individual customers that are predicted to be more likely to respond to promotions and marketing campaigns (Ling and Li 1998). Direct marketing is closely related to CRM as it is also based on the concept of customer differentiation and profiling. In addition, due to advanced web technologies, online social networks have become important channels for information disseminations and diffusion. As a result, network mining techniques have been used in

* Discriminant analysis is a type of statistical analysis used to express a categorical-dependent variable using a linear combination of a set of independent variables.

viral marketing programs (Domingos and Richardson 2001; Watts and Dodds 2007). By identifying and targeting the most influential customers in a company's online customer networks, the company may be able to spread the information about promotions of new products and services quickly through these customers, achieving high effectiveness with low costs. In addition, by analyzing the community structure in customer networks, companies may also obtain insights into customers' opinions and attitudes toward their products and services (Chau et al. 2009).

- *E-commerce*: KDD technologies have brought great opportunities for e-commerce. In addition to the patterns that can be mined using traditional data mining techniques such as association rules, classification, and clustering analysis, new patterns that are unique to the ways that customer use the websites can be extracted using web usage mining (Srivastava et al. 2000). For example, the paths along which customers navigate among web pages can help design personalized websites so as to provide better online shopping convenience and experience and to increase the chances of customer retention. In addition, web usage patterns can also help generate better recommendations of products using content-based approaches (i.e., recommending items similar to the items purchased in the past) or collaborative approaches (i.e., recommending items that are purchased by other customers).

19.3.3 Healthcare and Biomedicine

KDD has become increasingly popular in the domain of healthcare and biomedicine because of the availability of large-size databases and data warehouses for clinical records, gene sequences, and medical literature. However, the "information overload" problem also poses challenges to healthcare professionals (e.g., doctors, nurses, hospital officials, insurers, and pharmaceutical companies) and medical researchers. It is nearly impossible for anyone to process, analyze, and digest such large volumes of healthcare data to make correct, timely decision using manual approaches. Data mining technologies enable healthcare professionals and researchers to leverage healthcare data for the purposes of diagnosing diseases, developing effective treatments, drugs, nurse care plans, and novel hypotheses (Koh and Tan 2005), and detecting infectious disease outbreaks (Chapman et al. 2004; Zeng et al. 2005):

- *Disease diagnosis*: Data mining techniques, especially classification methods, have been used to help with the diagnosis and treatments of various diseases. For example, Breault et al. (2002) used the decision tree algorithm, CART, to classify over 30,000 records of diabetic patients in a large medical data warehouse and found that younger age was the most important variable associated with bad glycemic control. Similarly, Kaur and Wasan (2006) applied classification methods to the early diagnosis of type-I diabetes in children. Classification algorithms have also been used in the diagnosis of cancers and tumors (Ball et al. 2002; Delen et al. 2005), skin lesions (Dreiseitl et al. 2001), preterm birth (Prather et al. 1997), and neurological disorders (Xu et al. 2011).
- *Gene expression and microarray data analysis*: The advances in new biomedical technologies for genome sequencing and protein identification have brought tremendous opportunities for mining gene expression[*] and microarray data[†] (Getz et al. 2000; Sturn et al. 2002) to help develop personalized drugs and treatment for patients (Debouck and Goodfellow 1999), or find new biological solutions to medical problems. Clustering analysis is widely used on microarray data to identify tissue similarity or groups of genes sharing similar expression patterns (Matsumoto et al. 2003). Examples of these applications include using hierarchical clustering for identifying genome-wide expression patterns (Eisen et al. 1998), *k*-means for clustering complementary CDNA fingerprinting data (Herwig et al. 1999), hierarchical self-organizing methods for discovering cancer classes

---

* Gene expression is a process in which the genetic information encoded in a DNA stretch is used to synthesize a functional protein.

† A microarray is a two-dimensional array on a glass slide or silicon thin film that records the activities and interactions of a large amount of biological entities (e.g., genes, proteins, and antibodies) using high-throughput screening methods.

and identifying marker genes (Hsu et al. 2003), and neural network-based methods for finding gene groups that are consistent with those defined by functional categories and common regulatory motifs (Sawa and Ohno-Machado 2003).

- *Biomedical text analysis*: Text mining techniques have been used in recent years to analyze biomedical texts in the form of research articles, laboratory reports, clinical documents, and patient records to discover relationships between biological entities (e.g., genes, proteins, drugs, and diseases) that are potentially useful but previously unnoticed. For example, Kazama et al. (2002) used SVM to extract biological entities in the GENIA corpus. Tanabe and Wilbur (2002) used the part-of-speech tagging and a Bayesian model to extract genes and proteins in biomedical text. Biological relationships (e.g., gene regulations, metabolic pathways, and protein interactions) are identified using various text mining and data mining methods (Song and Chen 2009; Steele et al. 2009).

19.3.4 Security and Intelligence

In response to the tragic events of 9/11 and the following series of terrorist attacks around the world, there has been a pressing demand for advanced technologies for helping intelligence communities and law enforcement agencies combat terrorism and other crimes. A new interdisciplinary field called *Intelligence and Security Informatics* (*ISI*) (Chen et al. 2003) has emerged to leverage technologies and knowledge from different disciplines to assist crime investigation and help detect and prevent terrorist attacks. KDD is a core component in the ISI technology collection (Chen et al. 2003):

- *Crime investigation*: A number of data mining techniques have been employed in crime investigation applications. For example, classification and clustering techniques have been applied to detect various types of crimes including computer crimes. Adderley and Musgrove (2001) and Kangas et al. (2003) employed the SOM approach to cluster crime incidents based on a number of offender attributes (e.g., offender motives and racial preferences) to identify serial murders and sexual offenders. Ryan et al. (1998) developed a neural network-based intrusion detection method to identify unusual user activities based on the patterns of users' past system command usage. In addition, spatial pattern analysis and geographical profiling of crimes play important roles in solving crimes (Rossmo 1995). Brown (1998) proposed a k-means and nearest neighbor approach to cluster spatial data of crimes to find "hot spot" areas in a city (Murray and Estivill-Castro 1998). Koperski and Han (1995) used spatial association-rule mining to extract cause–effect relations among geographically referenced crime data to identify environmental factors that attract crimes (Estivill-Castro and Lee 2001).
- *Counterterrorism*: Terrorism and terrorist activities substantially threaten national security and have considerable negative impact on the society. However, because terrorist groups are covert organizations, the data about their members and activities are extremely difficult to gather. This has made knowledge discovery for counterterrorism a rather challenging task. Nonetheless, network mining techniques have been used to analyze and extract patterns from terrorist networks such as the Global Salafi Jihad networks (Sageman 2004) that were already destroyed by intelligence agencies. The structural characteristics and evolutional dynamics have been discovered using techniques such as community detection and topological analysis (Krebs 2001; Xu and Chen 2008; Xu et al. 2009). Although these findings were based on historical data, they enhanced our understanding of the organization, behavior, and characteristics of terrorist groups, and such understanding will help develop better strategies to prevent and fight future terrorist attacks (Krebs 2001; van Meter 2001; Dombroski and Carley 2002). In addition, because the web has been widely used by terrorist groups as a communication medium (Burris et al. 2000; Gerstenfeld et al. 2003), web mining techniques have been employed to discover patterns in the contents and structures of terrorist groups' websites (Chen 2012).

In addition to the application domains we have reviewed, KDD technologies have also made great impacts in a number of other domains such as sciences (Fayyad et al. 1996a), engineering (Grossman et al. 2001), and manufacturing (Harding et al. 2006), among many others.

19.4 Research Issues

Research on knowledge discovery and data mining has made considerable progress in recent years (Han et al. 2011). However, many issues still remain challenging. In addition, with the rapid innovation and development of technologies in database management, data collection, computer memory, and computational power, new trends and directions keep emerging in the field of KDD:

- *Diversity of data types*: The diversity of data types will continue to be both a challenge and an opportunity for KDD research. On one hand, more new data types have become available for mining purposes including web data (e.g., hyperlinks, web pages, and web usage data), multimedia data (e.g., videos, autos, and images), sequence data (e.g., time series, symbolic sequences, DNA sequences, and protein sequences), network data (e.g., social networks, computer networks, and information networks), spatiotemporal data, and data streams (e.g., sensor data). These new data types may pose unique challenges on traditional data management and mining technologies. For example, sensor data usually arrive rapidly and continuously, and traditional database management systems are not designed for loading such continuous streams. In addition, many mining algorithms can only access data via a few linear scans and generally cannot perform repeated random access on data streams (Yates and Xu 2010). On the other hand, these new data types also expose the KDD research to new areas and application domains. For example, image mining and spatiotemporal data mining can be used in mobile phones, global positioning system (GPS) devices, weather services, and satellites (Han et al. 2011). Mining on DNA sequence and microarray data may provide new insights and directions to the development of new drugs and medicine (Debouck and Goodfellow 1999).
- *High-performance mining techniques*: As the number of KDD applications continues to grow, the demand for developing new mining techniques with high performance remains strong. In addition to the improvement of general-purpose techniques such as classification and clustering, the development of application-specific algorithms is becoming a trend. Many applications have their unique goals, constraints, and characteristics, which require that the mining techniques be tailored to address the unique problems in the specific applications. For example, in network mining applications, traditional clustering algorithms based on similarity or distance measures could not be used to uncover community structure in unweighted networks since all links are of the same length (distance). As a result, non-distance-based methods need to be developed to address this problem (Clauset et al. 2004). Moreover, as the volumes of data continue to grow, the mining algorithms and methods must be scalable enough to mine large-scale datasets effectively and efficiently.
- *User interaction and domain knowledge*: The process of KDD should be made interactive so that users and analysts can set parameters, select techniques, specify constraints and conditions, and incorporate their domain knowledge to guide the mining process (Fayyad et al. 1996c). However, most existing data mining technologies are not interactive. To many users, the mining process is a black box over which they do not have any control. Another issue is concerning the presentation of KDD results. That is, the patterns generated should be presented in a way that users and analysts, who may not understand the technology, could easily interpret and comprehend them. This requires the development of effective knowledge presentation and visualization techniques to help users and analysts understand the discovered patterns and make correct, timely decisions based on the knowledge.
- *Evaluation and validation of mining results*: Since knowledge discovery is a process to extract novel patterns that are previously unknown, many data mining technologies are exploratory in nature. Unlike statistical results, which can be evaluated using standard tests, results generated

by data mining algorithms may not have standard tests available for assessing their "significance." The patterns yielded by hierarchical clustering algorithms, for example, are dendrograms, which can be cut at any similarity (or distance) level to produce a partition of the data. Except for domain experts' subjective evaluation, there is no "gold" standard for evaluating the quality or utility of a particular partition (Jain et al. 1999). Therefore, while developing new techniques and methods is important, it is also critical to develop appropriate evaluation and validation methods, in addition to existing methods and metrics (e.g., multiple-fold cross validation, accuracy, precision and recall), to ensure the quality of the extracted patterns.

- *Privacy concerns*: A recent trend in KDD research is on the privacy-preserving data mining due to the increasing concerns with data privacy and security. Especially in domains such as healthcare, medicine, and security and intelligence, confidential data (e.g., patients' medical history and criminals' identities) must be handled with great caution. There are established rules, regulations, and laws to protect privacy and confidentiality of data. The 1996 Health Insurance Portability and Accountability Act (HIPAA), for example, set the rules for handling patient records in electronic forms. Violations of such regulations may lead to serious social, ethical, or even legal consequences. Privacy-preserving data mining, therefore, is designed to extract knowledge from data without threatening the privacy and confidentially of records by using various transformation approaches such as data de-identification (Cios and Moore 2002), perturbation (Li and Sarkar 2006), or reconstruction (Zhu et al. 2009).

19.5 Summary

KDD is a fast-growing, interdisciplinary field. More than two decades of research and practice have resulted in significant progress in this field. This chapter introduces the principles and major techniques of data mining techniques including association mining, classification, clustering, and outlier analysis. Relatively new data mining topics such as text mining, web mining, and network mining are also discussed. Examples of application domains in which KDD has made tremendous impact include finance, business, marketing, healthcare, biomedicine, security, and intelligence. Although various issues remain to be challenging, the KDD field will keep growing and thriving with emerging new trends and directions.

20.1 Introduction to Big Data

Perhaps nothing will have as large an impact on advanced analytics in the coming years as the ongoing explosion of new and powerful data sources. When analyzing customers, for example, the days of relying exclusively on demographics and sales history are past. Virtually every industry has at least one completely new data source coming online soon, if it is not here already. Some of the data sources apply widely across industries; others are primarily relevant to a very small number of industries or niches. Many of these data sources fall under a new term that is receiving a lot of buzz: big data.

20.1.1 What Is Big Data?

There is not a consensus in the marketplace as to how to define big data, but there are a couple of consistent themes. Two sources have done a good job of capturing the essence of what most would agree big data is all about. The first definition is from Gartner's Merv Adrian in an early 2011 Teradata Magazine article. According to Adrian: "Big data exceeds the reach of commonly used hardware environments and software tools to capture, manage, and process it within a tolerable elapsed time for its user population" [1]. Another good definition is from a paper by the McKinsey Global Institute in May 2011: "Big data refers to data sets whose size is beyond the ability of typical database software tools to capture, store, manage and analyze" [2].

* Portions of this chapter have been adapted from: Taming the Big Data Tidal Wave: Finding the Opportunities in Huge Data Streams with Advanced Analytics, Bill Franks. Copyright ©2012 Bill Franks. Used with permission of John Wiley & Sons, Inc.

These definitions imply that what qualifies as big data will change over time as technology advances. What was big data historically or what is big data today will not be big data tomorrow. This aspect of the definition of big data is one that some people find unsettling. The preceding definitions also imply that what constitutes big data can vary by industry, or even organization, if the tools and technologies in place vary greatly in capability.

A couple of interesting facts reported in the McKinsey paper help bring into focus how much data is out there today:

1. $600 today can buy a disk drive that will store all of the world's recorded music.
2. There are 30 billion pieces of information shared on Facebook each month.
3. Fifteen of 17 industry sectors in the United States have more data per company on average than the U.S. Library of Congress [3].

Despite these impressive statistics, big data is not just about the size of the data in numbers of bytes. According to Gartner, the "big" in big data also refers to several other characteristics of a big data source [4]. These aspects include not just increased volume but increased velocity and increased variety. These factors, of course, lead to extra complexity as well. What this means is that you are not just getting a lot of data when you work with big data. It is also coming at you fast, it is coming at you in complex formats, and it is coming at you from a variety of sources.

The analytic techniques, processes, and systems within organizations will be strained up to, or even beyond, their limits. It will be necessary to develop additional analysis techniques and processes utilizing updated technologies and methods in order to analyze and act upon big data effectively. We will discuss these techniques later in the chapter.

20.1.2 How Is Big Data Different?

There are some important ways that big data is different from traditional data sources. Not every big data source will have every feature that follows, but most big data sources will have several of them.

First, big data is often automatically generated by a sensor or a machine. If you think about traditional data sources, there was always a person involved. Consider retail or bank transactions, telephone call detail records, product shipments, or invoice payments. All of those involve a person doing something in order for a data record to be generated. Somebody had to deposit money, or make a purchase, or make a phone call, or send a shipment, or make a payment. In each case, there is a person who is taking action as part of the process of new data being created. This is not so for big data in many cases. A lot of sources of big data is generated without any human interaction at all. A sensor embedded in an engine, for example, spits out data about its surroundings even when nobody touches it or asks it to.

Second, big data is typically an entirely new source of data. It is not simply an extended collection of existing data. For example, with the use of the Internet, customers can now execute a transaction with a bank or retailer online. But the transactions they execute are not fundamentally different transactions from what they would have done traditionally. They have simply executed the transactions through a different channel. An organization may capture web transactions, but they are really just more of the same old transactions that have been captured for years. However, actually capturing browsing behaviors as customers execute a transaction creates fundamentally new data, which represent a transition from analyzing only transactions to extending analysis to understand the interactions that lead up to (and follow) the transactions.

Sometimes, "more of the same" can be taken to such an extreme that the data becomes something new. For example, your power meter has probably been read manually each month for years. An argument can be made that automatic readings every 15 min by a smart meter is more of the same. It can also be argued that it is so much more of the same and that it enables such a different, more in-depth level of analytics that such data is really a new data source.

Third, many big data sources are not designed to be friendly. In fact, some of the sources are not designed at all! Take text streams from a social media site. There is no way to ask users to follow certain

standards of grammar, or sentence ordering, or vocabulary. You are going to get what you get when people make a posting. It is almost always difficult to work with such data at best and very, very ugly at worst. Most traditional data sources were designed up-front to be friendly. Systems used to capture transactions, for example, provide data in a clean, preformatted template that makes the data easy to load and use. This was driven, in part, by the historical need to be highly efficient with space. There was no room for excess fluff. Traditional data sources were very tightly defined up-front. Every bit of data had a high level of value or it would not be included. With the cost of storage space becoming almost negligible, big data sources are not always tightly defined up-front and typically capture everything that may be of use. This can lead to having to wade through messy, junk-filled data when performing an analysis.

Finally, large swaths of big data streams may not have much value. In fact, much of the data may even be close to worthless. Within a web log, there is information that is very powerful. There is also a lot of information that does not have much value at all. It is necessary to weed through and pull out the valuable and relevant pieces. Traditional data sources were defined up-front to be 100% relevant. This is because of the scalability limitations that were present. It was far too expensive to have anything included in a data feed that was not critical. Not only were data records predefined, but every piece of data in them was of high value. Storage space is no longer a primary constraint. This has led to the default with big data being to capture everything possible and worry later about what matters. This ensures nothing will be missed but also can make the process of analyzing big data more painful.

Big data will change some of the tactics analytic professionals use as they do their work. New tools, methods, and technologies will be added alongside traditional analytic tools to help deal more effectively with the flood of big data. Complex filtering algorithms will be developed to siphon off the meaningful pieces from a raw stream of big data. Not only SQL (NoSQL) programming methods for incorporating parallelization of procedural capabilities alongside traditional analytic tools, late-binding techniques for deferring the imposition of structure on top of nontraditional data, and polymorphic file systems for handling multi-structured data are key technologies that have emerged to exploit big data. Modeling and forecasting processes are being updated to include big data inputs on top of currently existing inputs. These tactical changes do not fundamentally alter the goals or purpose of analysis, or the analysis process itself.

20.1.3 Structure of Big Data

As you research big data, you will come across a lot of discussion on the concept of data being structured, unstructured, semi-structured, or even multi-structured. Big data is often described as unstructured and traditional data as structured. The lines are not as clean as such labels suggest, however. Most traditional data sources are fully in the structured realm. This means traditional data sources come in a clear, predefined format that is specified in detail. There is no variation from the defined formats on a day-to-day or update-to-update basis. For a stock trade, the first field received might be a date in a MM/DD/YYYY format, next might be an account number in a 12-digit numeric format, next might be a stock symbol that is a three- to five-digit character field, and so on. Every piece of information included is known ahead of time, comes in a specified format, and occurs in a specified order. This makes it easy to work with.

Unstructured data sources are those that you have little or no control over. You are going to get what you get. Text data, video data, and audio data all fall into this classification. Although all of these data types have structure, they do not fit well into traditional file systems or relational database technologies. For example, a picture has a format of individual pixels set up in rows, but how those pixels fit together to create the picture seen by an observer is going to vary substantially in each case. Trying to store a picture into a traditional file system using anything other than a binary large object (BLOB) format is difficult.

There are sources of big data that are truly unstructured such as those described earlier. However, most data is at least semi-structured. Semi-structured data has a logical flow and format that can be understood, but the format is not user-friendly. Sometimes semi-structured data is referred to as

```

```

FIGURE 20.1 Example of raw web log data.

multi-structured data. There can be a lot of noise or unnecessary data intermixed with the nuggets of high value in such a feed. Reading semi-structured data to analyze them is not as simple as specifying a fixed file format. To read semi-structured data, it is necessary to employ complex rules that dynamically determine how to proceed after reading each piece of information.

Web logs are a good example of semi-structured data. Web logs are pretty ugly when you look at them; however, each piece of information does, in fact, serve a purpose of some sort. Whether any given piece of a web log serves your purposes is another question (see Figure 20.1 for an example of a raw web log).

There is logic to the information in the web log even if it is not entirely clear at first glance. There are fields, there are delimiters, and there are values just like in a structured source. However, they do not follow each other consistently or in a set way. The log text generated by a click on a website right now can be longer or shorter than the log text generated by a click from a different page 1 min from now. In the end, however, it is important to understand that semi-structured data has an underlying logic. It is possible to develop relationships between various pieces of it. It simply takes more effort than structured data.

20.1.4 Filtering Big Data Effectively

The biggest challenge with big data may not be the analytics you do with it, but the extract, transform, and load (ETL) processes you have to build to get it ready for analysis. ETL is the process of taking a raw feed of data, reading it, and producing a usable set of output. The data is extracted (E) from whatever source it is starting from. The data is next transformed (T) through various aggregations, functions, and combinations to get it into a usable state. Finally, the data is loaded (L) into whatever environment will be leveraged to analyze the data. That is the process of ETL.

When you are drinking water out of a hose, you do not really care which parts of the stream of water get in your mouth. With big data, you care very much about which parts of the data stream get captured. It will be necessary to explore and understand the entire data stream first. Only then can you filter down to the pieces that you need. This is why the up-front effort to tackle big data can take so long. The goal is to sip the right amount of data out of the data stream as it flows past, not to try and drink it all. By focusing on the important pieces of the data, it makes big data easier to handle and keeps efforts focused on what is important.

Analytic processes may require filters on the front end to remove portions of a big data set when it first arrives in order to manage the economics of huge data streams. There will be additional filters along the way as the data is processed. The complexity of the rules and the magnitude of the data being removed or kept at each stage will vary by data source and by business problem. The load processes and filters that are put on top of big data is absolutely critical. Without getting those correct, it will be very difficult to succeed. Traditional structured data does not require as much effort in these areas since it is specified, understood, and standardized in advance. With big data, it is necessary to specify, understand, and standardize it as part of the analysis process in many cases.

Deferring the imposition of specific structure on the big data until the time of analysis provides a lot of flexibility in organizing the data in accordance with the needs of each analytic undertaking. Moreover, avoiding the high cost of ETL as an up-front prerequisite to data processing can lead to much greater agility in analytics. This "NoETL" approach to data processing means that there is a higher burden placed onto the analyst to extract the structure required from data at execution time for a query. This late-binding technique for big data analytics is particularly useful when content of the data changes quickly and is not well aligned to relational modeling structures.

20.2 Big Data Use Cases

If Web data is not the original big data, it is probably the most widely used and recognized source of big data. But there are many other sources of big data as well, and they all have their own valuable uses. Some are fairly well known and some are relatively obscure. The following sections provide a representative cross section of big data sources that go beyond web log data. The purpose of these examples is to illustrate the breadth and types of big data available, as well as the breadth of analysis that the data enables.

The big data sources we will cover include

- Auto insurance: The value of telematics data
- Multiple industries: The value of text data
- Multiple industries: The value of time and location data
- Retail and manufacturing: The value of radio-frequency identification (RFID) data
- Utilities: The value of smart-grid data
- Gaming: The value of casino chip tracking data
- Industrial engines and equipment: The value of sensor data
- Telecommunications and other industries: The value of social network data

20.2.1 Auto Insurance: The Value of Telematics Data

Telematics has started to receive serious attention in the auto insurance industry. Telematics involves putting a sensor, or black box, into a car to capture information about what is happening with the car. This black box can measure any number of things depending on how it is configured. It can monitor speed, mileage driven, or if there is a pattern of heavy braking. Telematics data help insurance companies better understand customer risk levels and set insurance rates. With telematics, it is possible to keep track of everywhere a car was driven, when it was there, how fast it was going, and what features of the car were in use.

There are insurance companies pursuing telematics-based insurance in many countries across the globe—and the number is growing. Early programs focus on collecting minimal information from cars. What the early programs do track is how far a car is driven, what time of day it is driven, and if speeding occurs. This is fairly basic information with limited privacy concerns, which is intentional. Using this basic information allows discounts to be granted for safer driving behaviors—incenting good driving habits and retaining lowest risk driving insurance customers.

Telematics data is taking hold initially as a tool to help consumers and companies get better, more effective auto and fleet insurance. Over time, telematics devices may end up being present in a large number of vehicles, and uses for telematics data outside of insurance will emerge. There are already onboard computers managing systems within an automobile, but a telematics device can take it to an entirely new level. There are some very interesting uses for telematics data.

Imagine that a critical mass of millions or tens of millions of cars end up with telematics devices within your country. Let's also imagine that a third-party research firm arranges with consumers to collect very detailed telematics data from their cars in an anonymous fashion. As opposed to the limited

data collected for insurance purposes, the data in this case has minute-by-minute or second-by-second updates on speed, location, direction, and other useful information.

This data feed will provide information on thousands of cars in any given traffic jam on any given day. Researchers will know how fast each car was moving along the way. They will know where traffic started, where it ended, and how long it lasted. This is an amazingly detailed view of the reality of traffic flow. Imagine the impact on the study of traffic jams and the planning of road systems! In fact, much of this data can be collected from location-enabled smart phones in geographies where these devices are highly penetrated.

The wealth of possibilities for telematics data is a terrific example of putting big data to use in a way that was not initially foreseen. Often, the most powerful uses for a given data source will be something entirely different from why it was created. Be sure to consider alternative uses for every big data stream encountered. Once researchers have access to thousands of cars in every rush hour, every day, in every city, they will have the ability to diagnose traffic causes and effects in immense detail. They will be able to pinpoint the answers to questions such as

- How does a tire in the road impact traffic?
- What happens if a left lane gets blocked?
- When a traffic light gets out of sync, what are the effects?
- Which traffic intersections are poorly timed, even if they are acting the way they were programmed to act?
- How fast does a backup in one lane spread to other lanes?

It has traditionally been very difficult to effectively study such questions today, outside of very focused and expensive testing. It is possible to physically send people out to monitor a given stretch of road and record information, to put down sensors to count cars that go by, or to install a video camera. But those options are very limited in practice due to costs.

It is a traffic engineer's dream to have access to the telematics information outlined here. If telematics devices do become common, any location populated enough to have traffic can be studied. The changes that are made to roads and traffic management systems, as well as the plans for how roads are built in the first place, will provide huge benefits to all of us. Telematics got its start as a mechanism to assist in insurance pricing. But it may well revolutionize how we manage our highway systems and improve our lives by reducing the stress and frustration we experience when sitting in traffic.

20.2.2 Multiple Industries: The Value of Text Data

Text is one of the highest volume and most common sources of big data. Just imagine how much text is out there. There are e-mails, text messages, tweets, social media postings, instant messages, real-time chats, and audio recordings that have been translated into text. Text data is one of the least structured and largest sources of big data in existence today.

Luckily, a lot of work has been done already to tame text data and utilize it to make better business decisions. Text analytics typically starts by parsing text and assigning meaning to the various words, phrases, and components that comprise it. This can be done by simple frequency counts or more sophisticated methods. The discipline of natural language processing (NLP) comes into play heavily in such analytics.

Text mining tools are available as part of major analytic tool suites, and there are also stand-alone text mining packages available. Some of these text analysis tools focus on a rules-based approach where analysts have to tune the software to identify the patterns that they are interested in. Others use machine learning and advanced algorithms that help to find patterns within the data automatically.

Once the parsing and classification phases for preparing text are completed, the results of those processes can be analyzed. The output of a text mining exercise is often an input to other analytic processes. For example, once the sentiment of a customer's e-mail is identified, it is possible to generate a variable

that tags the customer's sentiment as negative or positive. That tag is now a piece of structured data that can be fed into an analytic process. Creating structured data out of unstructured text is often called information extraction.

For another example, assume that we have identified which specific products a customer commented about in his or her communications with our company. We can then generate a set of variables that identify the products discussed by the customer. Those variables are again metrics that are structured and can be used for analysis purposes. These examples illustrate how it is possible to capture pieces of unstructured data and create relevant and structured data from them.

Text analysis with NLP techniques is an excellent example of taking purely unstructured data, processing it, and creating structured data that can be used by traditional analytics and reporting processes. One major part of effectively exploiting big data is getting creative in the ways that unstructured and semi-structured data is made usable in this way.

Interpreting text data is actually quite difficult. The words we say change meaning based on which words we emphasize and also the context in which we state them. When looking at pure text, you will not know where the emphasis was placed, and you often will not know the full context. This means that an analyst must make some assumptions when deriving meaning from pure text data. In this way, text analysis is both an art and a science, and it will always involve a level of uncertainty. When performing text analysis, there will be issues with misclassification as well as issues with ambiguity. This is to be expected. If a pattern can be found within a set of text that enables a better decision to be made, then it should be used—even if the results are not perfect. The goal of text analysis is improvement of the decisions being made, not perfection. Text data can easily cross the bar of improving decisions and providing better information than was present without it. This is true even given the noise and ambiguity that text data contains.

A popular use of text analysis is "sentiment" analysis. Sentiment analysis looks at the general direction of opinion across a large number of people to provide information on what the market is saying, thinking, and feeling about a brand, product, or action associated with an organization. It often uses data from social media sites. Examples include the following:

- What is the "buzz" around a company or product?
- Which corporate initiatives are people talking about?
- Are people saying good or bad things about an organization and the products and services it offers?

One tough part of text analysis is that words can be good or bad depending on the context. It will be necessary to take that into account, but across a lot of individuals, the direction of sentiment should become clear. Getting a read on the trends of what people are saying across social media outlets or within customer service interactions can be immensely valuable in planning what to do next.

If an organization captures sentiment information at an individual customer level, it will provide a view into customer intent and attitudes. Similar to how it is possible to use web data to infer intent, knowing whether a customer's general sentiment about a product is positive or negative is valuable information. This is particularly true if the customer has not yet purchased that product. Sentiment analysis will provide information on how easy it is going to be to convince a specific customer to purchase a specific product.

Another use for text data is pattern recognition. By sorting through complaints, repair notes, and other comments made by customers, an organization will be more quickly able to identify and fix problems before they become bigger issues. As a product is first released and complaints start to come in, text analysis can identify the specific areas where customers are having problems. It may even be possible to identify a brewing issue in advance of a wave of customer service calls coming in. This will enable a much faster, more proactive reaction. The corporate response will be better both in terms of putting in place a fix to address the problem in future products and also in what can be done to reach out to customers and mitigate the issues that they are experiencing today.

Fraud detection is also a major application for text data. Within property and casualty or disability insurance claims, for example, it is possible to use text analysis to parse out the comments and justifications that have been submitted to identify patterns that are associated with fraud. Claims can be analyzed and scored based on the text content to flag high risk of fraud. Claims with higher risk patterns can be checked much more carefully. On the flip side, it is possible to enhance automation of claims adjudication. If there are patterns, terms, and phrases that are associated with clean, valid claims, those claims can be identified as low risk and can be expedited through the system, while claim examiners are more appropriately focused on the claims that have a higher risk.

The legal profession also benefits from text analysis. In a legal case, it is routine that e-mail or other communication histories are subpoenaed. The messages are then examined in bulk to identify statements that may contain information tied to the case at hand. For example, which e-mails have potential insider information in them? Which people made fraudulent statements as they interacted with others? What is the specific nature of threats that were made? Applying such analytics in a legal setting is often called eDiscovery. All of the preceding analytics can lead to successful prosecutions. Without text analysis, it would be almost impossible to manually scan all the documents required. Even if an effort was made to manually scan them, there would be a good chance of missing key information due to the monotonous nature of the task.

Text data has the potential to impact almost every industry. It is one of the most widely used forms of big data.

20.2.3 Multiple Industries: The Value of Time and Location Data

With the advent of global positioning systems (GPS), personal GPS devices, and cellular phones, time and location information is a growing source of data. A wide variety of services and applications including foursquare, Google Places, and Facebook Places are centered on registering where a person is located at a given point in time. Cell phone applications can record your location and movement on your behalf. Cell phones can even provide a fairly accurate location using cell tower signals if a phone is not formally GPS-enabled.

There are some very novel ways that consumer applications use this information, which leads to individuals allowing it to be captured. For example, there are applications that allow you to track the exact routes you travel when you exercise, how long the routes are, and how long it takes you to complete the routes. If you carry a cell phone, you can keep a record of everywhere you have been. You can also open up that data to others if you choose. As more individuals open up their time and location data more publicly, very interesting possibilities start to emerge.

Many organizations are starting to realize the power of knowing "when" their customers are "where" and are attempting to get permission to collect such information from their customers. Today, organizations are coming up with compelling value propositions to convince customers to release time and location information to them.

Time and location data is not just about consumers, however. The owner of a fleet of trucks is going to want to know where each is at any point in time. A pizza restaurant will want to know where each delivery person is at any given moment. Pet owners want to be able to locate pets if they get out of the house. A large banquet facility wants to know how efficiently servers are moving around and covering patrons in all areas of the facility.

As an organization collects time and location data on individual people and assets, it starts to get into the realm of big data quickly. This is especially true if frequent updates to that information are made. It is one thing to know where every truck ends up at the start and end of every day. It is another thing to know where every truck is every second of every day. Time and location data is going to continue to grow in adoption, application, and impact.

One application of these data that is only beginning to be leveraged is the development of time and location sensitive offers. It is no longer just about what offer to develop for a customer today or this

week but rather what offer is best for that customer based on when they will be where. Today, this is typically achieved by having customers check in and report where they are so they can receive an offer. Eventually, organizations may track the whereabouts of customers continually and react as necessary (with permission of the customer, of course).

Time and location data not only helps understand consumers' historical patterns but also allows accurate prediction where consumers will be in the future. This is especially true for consumers who stick to a regular schedule. If you know where a given person is and where they are heading, you can predict where they might be in 10 min or an hour based on that information. By looking at where consumers were going historically when on the same route, you can make an even more educated prediction as to where they are going now. At minimum, you can greatly narrow down the list of possibilities. This enables better targeting.

There is likely to be an explosion in the use of time and location data in the coming years. Opt-in processes and incentives for consumers will begin to mature. This will enable messaging to become even more targeted and personal than it is today. The idea of getting offers that are not targeted to the here and now may well be considered old-fashioned in the not-too-distant future.

20.2.4 Retail and Manufacturing: The Value of Radio-Frequency Identification Data

An RFID tag is a small tag placed on objects like shipping pallets or product packages. It is important to note that an RFID tag contains a unique serial number, as opposed to a generic product identifier like a universal product code (UPC) code. In other words, it does not just identify that a pallet contains some Model 123 computers. It identifies the pallet as being a specific, unique set of Model 123 computers.

When an RFID reader sends out a signal, the RFID tag responds by sending information back. It is possible to have many tags respond to one query if they are all within range of the reader. This makes accounting for a lot of items easy. Even when items are stacked on top of one another or behind a wall, as long as the signals can penetrate, it will be possible to get a response. RFID tags remove the need to manually log or inventory each item and allow a census to be taken much more rapidly.

Most RFID tags used outside of very-high-value applications are known as passive. This means that the tags do not have an embedded battery. The radio waves from a reader create a magnetic field that is used to provide just enough power to allow a tag to send out the information embedded within it. While RFID technology has been around for a long time, costs were prohibitive for most applications. Today, a passive tag costs just a few cents and prices continue to drop. As prices continue to drop, the feasible uses will continue to expand. There are some technical issues with today's RFID technology. One example is that liquids can block signals. As time progresses, these issues should be solved with updates to the technologies used.

There are uses of RFID today that most people will have come in contact with. One use is the automated toll tags that allow drivers to pass through a toll booth on a highway without stopping. The way it works is that the card provided by the toll authority has an RFID tag in it. There are also readers placed on the road. As a car drives through, the tag will transmit back the car's data so that the fact that you went through the toll can be registered.

Another major use of RFID data is asset tracking. For example, an organization might tag every single PC, desk, or television that it owns. Such tags enable robust inventory tracking. They also enable alerts if items are moved outside of approved areas. For example, readers might be placed by exits. If a corporate asset moves through the door without having been granted prior approval, an alarm can be sounded and security can be alerted. This is similar to how the item tags at retail stores sound an alarm if they have not been deactivated.

One of the biggest uses for RFID today is item and pallet tracking in the manufacturing and retail spaces. Each pallet a manufacturer sends to a retailer, for example, may have a tag. It makes it easy to take stock of what is in a given distribution center or store. Eventually, it is possible that every individual

product in a store that is above a trivial price point will end up being tagged with an RFID chip or an updated technology that serves the same purpose. Let's look at some examples of how RFID data can be used [5].

One application where RFID can add value is in identifying situations where an item has no units on the shelf in a retail environment. If a reader is constantly polling the shelves to identify how many of each item remains, it can provide an alert when restocking is needed. RFID enables much better tracking of shelf availability because there is a key difference between being out of stock and having shelf availability. It is entirely possible that the shelf in a store has no product on it, yet simultaneously there are five cases in the storage room in the back. In such a scenario, any traditional out-of-stock analysis is going to show that there is plenty of stock remaining and nothing to worry about. When sales start to drop, people are going to wonder why. If products have an RFID tag, it is possible to identify that there are five units in the back, yet no product on the shelf. As a result, the problem can be fixed by moving product from the back room to the shelf. There are some challenges in terms of cost and technology in this example today, but work is being done to overcome them.

RFID can also be a big help for tracking the impact of promotional displays. Often, during a promotion, product may be displayed in multiple locations throughout a store. From traditional point-of-sale data, all that will be known is that an item on promotion sold. It is not possible to know which display it came from. Through RFID tags, it is possible to identify which products were pulled from which displays. That makes it possible to assess how different locations in the store impact performance.

As RFID is combined with other data, it gets even more powerful. If a company has been collecting temperature data within a distribution center, product spoilage can be traced for items that were present during a specific power outage or other extreme event. Perhaps the temperature of a section of a warehouse got up to 90° for 90 min during a power outage. With RFID, it is possible to know exactly which pallets were in that part of distribution center at exactly that point in time and appropriate action can be taken. The warehouse data can then be matched to shipment data. A targeted recall can be issued if the products were likely to be damaged or retailers can be alerted to double-check their product as it arrives.

There are operational applications as well. Some distribution centers may tend to be too rough with merchandise and cause a high level of breakage. Perhaps this is true only for specific work teams or even specific workers. A human resources (HR) system will report who was working at any point in time. By combining that data with RFID data that show when product was moved, it is possible to identify employees who have an unusually high rate of breakage, shrinkage, and theft. The combination of data allows stronger, better quality action.

A very interesting future application of RFID is tracking store shopping in a similar fashion as web shopping. If RFID readers are placed in shopping carts, it is possible to know exactly what customers put into their carts and exactly what order that they added those items. Even if individual items are not tagged, the cart's path can still be identified. Many of the advantages of analyzing web data in an online environment can be re-created in a store environment through such a use of RFID.

RFID has the potential to have huge implications within the manufacturing and retail industries in the years to come. It has had a slower adoption rate than many expected. But as tag prices continue to drop and the quality of the tags and readers continues to improve, it will eventually make financial sense to pursue wider adoption.

20.2.5 Utilities: The Value of Smart-Grid Data

Smart grids are the next generation of electrical power infrastructure. A smart grid is much more advanced and robust than the traditional transmission lines all around us. A smart grid has highly sophisticated monitoring, communications, and generation systems that enable more consistent service and better recovery from outages or other problems. Various sensors and monitors keep tabs on many aspects of the power grid itself and the electricity flowing through it.

One aspect of a smart grid is what is known as a smart meter. A smart meter is an electric meter that replaces traditional meters. On the surface, a smart meter will not look much different than the meters we have always had. A smart meter is, however, much more functional than a traditional meter. Instead of a human meter reader having to physically visit a property and manually record consumption every few weeks or months, a smart meter automatically collects data on a regular basis, typically every 15 min to every hour. As a result, it is possible to have a much more robust view of power usage both for every household or business individually, as well as across a neighborhood or even the entire grid.

While we will focus on smart meters here, the sensors placed throughout a smart grid deserve a mention. The data that utilities capture from unseen sensors placed throughout the smart grid dwarf smart meter data in size. Synchrophasors that take 60 readings per second across the power system and home area networks recording each appliance cycling on or off are just two examples. The average person will not have any idea that most of these other sensors exist, but they will be crucial for the utilities. Such sensors will capture a full range of data on the flow of power and the state of equipment throughout the power grid. The data generated will be very, very big.

Smart-grid technology is already in place in some parts of Europe and the United States of America. Virtually, every power grid in the world will be replaced with smart-grid technology over time. The amount of data on electricity usage that utility companies will have available to them as a result of smart grids is going to grow exponentially.

From a power management perspective, the data from smart meters will help people to better understand demand levels from customers all the way up the chain. But the data can also benefit consumers. An individual homeowner, for example, will be able to explicitly test how much power various appliances use by simply turning them on while holding other things constant and then monitoring the detailed power usage statistics that flow from their smart meter.

Utilities around the world are already aggressively moving to pricing models that vary by time of day or demand, and the smart grid will only accelerate that. One of the primary goals of the utility firms is to utilize new pricing programs to influence customer behavior and reduce the demand during peak times. It is the peaks that require additional generation to be built, which drives significant costs and environmental impacts. If the cost of power can be flexibly applied by time of day and measured by the meter, customers can be incented to change their behavior. Lower peaks and more even demand equate to fewer new infrastructure requirements and lower costs.

The power company, of course, will be able to identify all sorts of additional trends through the data provided by smart meters. Which locations are drawing power on off-peak cycles? What customers have a similar daily or weekly cycle of power needs? A utility can segment customers based on usage patterns and develop products and programs that target specific segments. The data will also enable identification of specific locations that appear to have very unusual patterns that might point to problems needing correction.

In effect, power companies will have the ability to do all of the customer analytics other industries have been able to do for years. Imagine a phone company knowing your month-end total bill, but none of your calls. Consider a retailer knowing only your total sales, but none of your purchase details. Think about a financial institution knowing only your month-end balances, but none of the movements of money and funds throughout the month. In many ways, power companies have been dealing with data that are equally poor for understanding their customers. They had a simple month-end total usage, and even that month-end figure was often an estimated, not an actual, usage amount.

With smart meter data, a whole variety of new analytics will be enabled that will benefit all. Consumers will have customized rate plans based on their individual usage patterns, similar to how telematics enables individualized rates for auto insurance. A customer who is using power during peak periods is going to be charged more than nonpeak users. Such differentiated pricing will encourage consumers to shift usage patterns once they are able to see the incentives to do so. Perhaps consumers will run the dishwasher early in the evening instead of right after lunch, for example.

Utilities will have much better forecasts of demand as they are able to identify where demand is coming from in more detail. They will know what types of customers are demanding power at what points in time. The utility can look for ways to drive different behaviors to even out demand and lower the frequency of unusual spikes in demand. All of this will limit the need for expensive new-generation facilities.

Each household or business will gain the capability through smart meter data to better track and proactively manage its energy usage. This will not only save energy and make the world more green, but it is going to help everyone save money. After all, if you are able to identify where you are spending more than you intended, you will adjust as needed. With only a monthly bill, it is impossible to identify such opportunities. Smart meter data makes it simple.

In some cases, big data will literally transform an industry and allow it to take the use of analytics to a whole new level. Smart-grid data in the utility industry is an example. No longer limited by monthly meter readings, information on usage will be available at intervals measured in seconds or minutes. Add to that the sophisticated sensors throughout the grid, and it is a whole different world from a data perspective. The analysis of these data will lead to innovation in rate plans, power management, and more.

20.2.6 Gaming: The Value of Casino Chip Tracking Data

Earlier, we discussed RFID technology as it is applied to the retail and manufacturing industries. However, RFID technology has a wide range of uses, many of which lead to big data. An interesting use for RFID tags is to place them within the chips at a casino. Each chip, particularly high-value chips, can have its own embedded tag so that it can be uniquely identified via the tag's serial number.

Within a casino environment, slot machine play has been tracked for many years. Once you slide your frequent-player card in the machine, every time you pull the handle or push a button, it is tracked. Of course, so are the amounts of your wagers and any payouts that you receive. Robust analysis of slot patterns has been possible for years. However, casinos did not traditionally have the capacity to capture such details from table games. By embedding tags within gaming chips, they are now evolving to have it.

One obvious benefit of casino chip tags is the ability to precisely track each player's wagers. This ensures a player gets full credit in a frequent-player program, but no more or less. This benefits players and the casino. For the casino, resources will be allocated more precisely to the correct players. Over-rewarding the wrong players and under-rewarding the right players both lead to suboptimal allocation of limited marketing resources. Players, of course, always want their credits to be accurate.

Wager data collected across players will allow casinos to better segment players and understand betting patterns. Who typically bets $5 at a time, yet every once in a while jumps up to a $100 bet? Who bets $10 every time? Players can be segmented based on these patterns. The betting patterns can also point to those who are card counting in blackjack as there are certain patterns of wagers that will become clear when a player is using card counting techniques.

With chip tracking, it is also a lot harder to purposely defraud a casino or even for a dealer to make a mistake. Since bets and payouts can be tracked to the chip, it is easy to go back and compare video of the results of a blackjack hand and the payouts that were made. Even if arms or heads obscure what chips were put down or picked up, the RFID readings will provide the details. It will allow casinos to identify errors or fraud that took place. One example is when a player puts down extra chips after the fact when the dealer is looking the other way.

Analysis over time can identify dealers or players involved in an unusual number of mistakes. This will lead to either addressing fraudulent activity or providing additional training for a dealer who just happens to make a lot of innocent mistakes. Errors will also be lowered in the counting of chips in the casino cage. Counting large stacks of chips of different denomination is monotonous, and people can make mistakes. RFID allows faster, more accurate tallying.

Taking the preceding example further, the tracking of individual chips is a strong deterrent for thieves. If a stack of chips is stolen, the RFID identifiers for those chips can be flagged as stolen. When someone comes in to cash the chips, or even sits at a table with the chips, the system can realize it and alert security. If thieves remove or alter the chips so that they cannot be read, that will be a flag. The casino will know exactly what chip IDs exist and will expect each chip to report a valid ID. When a chip does not report an ID, or when the ID reported is not valid, they can take action.

As with any business, the more a casino can stop fraud and ensure that appropriate payouts are being made, the less risk it has. This will lead to the ability to provide both better service and better odds to players since there will be fewer expenses to cover. It can be a win for both casinos and their players.

Retailers and manufacturers leverage RFID technology. So do casinos. How they use RFID is totally different in many ways and has similarities in others. The interesting part is that a single technology can be used by different industries to create their own distinct sources of big data. These examples illustrate that some of the same underlying technologies will enable different big data streams that are similar in nature but completely different in scope and application. One fundamental technology can have different and completely distinct uses that generate multiple forms of big data in multiple industries.

20.2.7 Industrial Engines and Equipment: The Value of Sensor Data

There are a lot of complex machines and engines in the world. These include aircraft, trains, military vehicles, construction equipment, drilling equipment, and others. Keeping such equipment running smoothly is absolutely critical given how much it costs. In recent years, embedded sensors have begun to be utilized in everything from aircraft engines to tanks in order to monitor the second-by-second or millisecond-by-millisecond status of the equipment.

Monitoring may be done in immense detail, particularly during testing and development. For example, as a new engine is developed, it is worth capturing as much detailed data as possible to identify if it is working as expected. It is quite expensive to replace a flawed component once an engine is released, so it is necessary to analyze performance carefully up-front. Monitoring is also an ongoing endeavor. Perhaps not every detail is captured for every millisecond on an ongoing basis, but a large amount of detail is captured in order to assess equipment lifecycles and identify recurring issues.

Consider an engine. A sensor can capture everything from temperature, to revolutions per minute, to fuel intake rate, to oil pressure level. These data can be captured as frequently as desired. All of these data get massive quickly as the frequency of readings, number of metrics being read, and number of items being monitored in such a fashion increases.

Engines are very complex. They contain many moving parts, must operate at high temperatures, and experience a wide range of operating conditions. Because of their cost, they are expected to last many years. Stable and predictable performance is crucial, and lives often quite literally depend on it. For example, taking an aircraft out of service for maintenance will cost an airline or a country's air force a lot of money, but it must be done if a safety issue is identified. It is imperative to minimize the time that aircraft and aircraft engines, as well as other equipment, are out of service.

Strategies for minimizing down time include holding spare parts or engines that can be quickly swapped for the asset requiring maintenance, creating diagnostics to quickly identify the parts that must be replaced, and investing in more reliable versions of problem parts. All three of these strategies depend on data for effective implementation. Data is used to create diagnostic algorithms and as input to the algorithms to diagnose a specific problem. Engineering organizations can use sensor data to pinpoint the underlying causes of failure and design new safeguards for longer, more dependable operation. These considerations apply whether the engine is in an aircraft, watercraft, or ground-based equipment.

By capturing and analyzing detailed data on engine operations, it is possible to pinpoint specific patterns that lead to imminent failures. Patterns over time that lead to lower engine life and/or more frequent repair can also be identified. The number of permutations of the various readings, especially over time, makes analysis of these data a challenge. Not only does the process involve big data, but the

analysis that must be developed is complex and difficult. Some examples of the types of questions that can be studied are as follows:

- Does a sudden drop in pressure indicate imminent failure with near certainty?
- Does a steady decrease in temperature over a period of a few hours point to other problems?
- What do unusual vibration levels imply?
- Does heavy engine revving upon start-up seriously degrade certain components and increase the frequency of maintenance required?
- Does a slightly low fuel pressure over a period of months lead to damage to some of the engine's components?

When major problems arise, it is extremely helpful to go back and examine what was taking place in the moments up until the problem manifested itself. In this case, sensors act similarly to how well-known airplane black boxes help diagnose the cause of an accident. The data from the sensors in an engine also provide data that can be leveraged for diagnostic and research purposes. The sensors being discussed here are conceptually a more sophisticated form of the telematics devices discussed in the auto insurance example. The use of data from sensors that are continually surveying their surroundings is a recurrent theme in the world of big data. While we have focused on engines here, there are countless other ways that sensors are also being used today, and the same principles discussed here apply to those uses.

If the sensor data capture process is repeated across a lot of engines and a long period of time, it leads to a wealth of data to analyze. Analyze it well, and it is possible to find glitches in equipment that can be proactively fixed. Weak points can also be identified. Then, procedures can be developed to mitigate the problems that result from those findings. The benefits are not just added safety but also lowered cost. As sensor data enables safer engines and equipment that remain in service a higher percentage of the time, it will enable both smoother operations and lower costs.

Sensor data offers a difficult challenge. While the data collected is structured and its individual data elements are well understood, the relationships and patterns between the elements over time may not be understood at all. Time delays and unmeasured external factors can add to the problem's difficulty. The process of identifying the long-term interactions of various readings is extremely difficult given all the information to consider. Having structured data does not guarantee a highly structured and standardized approach to analyzing it.

20.2.8 Telecommunications and Other Industries: The Value of Social Network Data

Social network data qualifies as a big data source even though in many ways it is more of an analysis methodology against traditional data. The reason is that the process of executing social network analysis requires taking data sets that are already large and using them in a way that effectively increases their size by orders of magnitude.

One could argue that the complete set of cell phone calls or text message records captured by a cellular carrier is big data in and of itself. Such data is routinely used for a variety of purposes. Social network analysis, however, is going to take it up a notch by looking into several degrees of association instead of just one. That is why social network analysis can turn traditional data sources into big data.

For a modern phone company, it is no longer sufficient to look at all callers and analyze them as individual entities. With social network analysis, it is necessary to look at whom the calls were between and then extend that view deeper. You need to know not only whom I called but also whom the people I called in turn called, and whom those people in turn called, and so on. To get a more complete picture of a social network, it is possible to go as many layers deep as analysis systems can handle. The need to navigate from customer to customer and call to call for several layers makes the volume of data become multiplied. It also increases the difficulty of analyzing it, particularly when it comes to traditional tools.

The same concepts apply to social networking sites. When analyzing any given member of a social network, it is not that hard to identify how many connections the member has, how often she posts messages, how often she visits the site, and other standard metrics. However, knowing how wide a network a given member has when including friends, friends of friends, and friends of friends of friends requires much more processing.

One thousand members or subscribers are not hard to keep track of. But they can have up to one million direct connections between them and up to one billion connections when "friends of friends" are considered. That is why social networking analysis is a big data problem. The analysis of such connections has a number of applications being pursued today. Moreover, social network analysis will typically use graph structures and sophisticated graph algorithms for calculation of social network metrics. While graphs can be represented by casting them into relational structures, a native representation of graphs with the ability to parallelize graph operators is very useful for this type of analysis.

Social network data, and the analysis of it, has some high-impact applications. One important application is changing the way organizations value customers. Instead of solely looking at a customer's individual value, it is now possible to explore the value of his or her overall network. The example we are about to discuss could apply to a wide range of other industries where relationships between people or groups are known, but we will focus on wireless phones since that is where the methods have been most widely adopted.

Assume a wireless carrier has a relatively low-value customer as a subscriber. The customer has only a basic call plan and does not generate any ancillary revenue. In fact, the customer is barely profitable, if the customer generates profit at all. A carrier would traditionally value this customer based on his or her individual account. Historically speaking, when such a customer calls to complain and threaten to leave, the company may have let the customer go. The customer just is not worth the cost of retention.

With social network analysis, it is possible to identify that the few people our customer does call on that inexpensive calling plan are very heavy users who have very wide networks of friends. In other words, the connections that customer has are very valuable to the organization. Studies have shown that once one member of a calling circle leaves, others are more likely to leave and follow the first. As more members of the circle leave, it can catch like a contagion and soon circle members are dropping fast. This is obviously a bad thing.

A very compelling benefit of social network data is the ability to identify the total revenue that a customer influences rather than just the direct revenue that he or she provides. This can lead to drastically different decisions about how to invest in that customer. A highly influential customer needs to be coddled well beyond what his or her direct value indicates if maximizing a network's total profitability takes priority over maximizing each account's individual profitability.

Using social network analysis, it is possible to understand the total value that the customer in our example influences for the organization rather than only the revenue directly generated. This allows a completely different decision regarding how to handle that customer. The wireless carrier may overinvest in the customer to make sure that they protect the network the customer is a part of. A business case can be made to provide incentives that dwarf the customer's individual value if doing so will protect the wider circle of customers that he or she is a part of.

This is an excellent example of how the analysis of big data can help provide new contexts in which decisions that would have never happened in the past now make perfect sense. Without big data, the customer would have been allowed to cancel and the wireless carrier would not have seen the avalanche of losses that soon came as the customer's friends followed. The goal shifts from maximizing individual account profitability to maximizing the profitability of the customer's network.

Identification of highly connected customers can also pinpoint where to focus efforts to influence brand image. Highly connected customers can be provided free trials and their feedback can be solicited. Attempts can be made to get them active on corporate social networking sites through incentives to provide commentary and opinion. Some organizations actively recruit influential customers and shower them with perks, advance trials, and other goodies. In return, those

influential customers continue to wield their influence, and it should be even more positive in tone given the special treatment they are receiving.

Within social networking sites like LinkedIn or Facebook, social network analysis can yield insights into what advertisements might appeal to given users. This is done by considering not just the interests customers have personally stated. Equally important, it is based on knowing what their circle of friends or colleagues has an interest in. Members will never declare all of their interests on a social networking site, and every detail about them will never be known. However, if a good portion of a customer's friends have an interest in biking, for example, it can be inferred that the customer does as well, even though the customer might never have stated that directly.

Law enforcement and antiterrorism efforts can leverage social network analysis. Is it possible to identify people who are linked, even if indirectly, to known trouble groups or persons? Analysis of this type is often referred to as link analysis. It could be an individual, a group, or even a club or restaurant that is known to attract a bad element. If a person is found to be hanging out with a lot of these elements in a lot of these places, he or she might be targeted for a deeper look. While this is another analysis that raises privacy concerns, it is being used in real life situations today.

Online video gaming is another area where such analysis can be valuable. Who plays with whom? How does that pattern change across games? It is possible to identify a player's preferred partners on a game-by-game basis. Telemetry data makes it possible for players to be segmented based on individual playing style. Do players of similar styles team up when playing together? Or do players seek a mix of styles? Knowing such information can be valuable to know if a game producer wants to suggest groups for players to team up with (e.g., providing suggestions as to which group, out of the many options available in a list, a player might prefer to join in with when he or she logs in to play).

There have also been interesting studies on how organizations are connected. It starts by looking at the connections established through e-mail, phone calls, and text messages within an organization. Are departments interacting as expected? Are some employees going outside typical channels to make things happen? Who has a wide internal influence and would be a good person to take part in a study on how to better improve communications within the organization? This type of analysis can help organizations better understand how their people communicate.

Social network analysis will continue to grow in prevalence and impact. One of the interesting features it has is that it is always going to make a data source much bigger than it began due to the exponentially expanding nature of the analysis process. Perhaps the most appealing feature is how it can provide insights into a customer's total influence and value, which can completely change how that customer is viewed by an organization.

20.3 Big Data Technologies

It goes without saying that the world of big data requires new levels of scalability. As the amount of data organizations process continues to increase, the same old methods for handling data just will not work anymore. Organizations that do not update their technologies to provide a higher level of scalability will quite simply choke on big data. Luckily, there are multiple technologies available that address different aspects of the process of taming big data and making use of it in analytic processes. Three key technologies that are essential components of most big data deployment strategies are as follows: (1) massively parallel processing (MPP) systems, (2) cloud computing, and (3) MapReduce.

20.3.1 Massively Parallel Processing Systems

MPP systems have been around for decades. While the specifics of individual vendor implementations may vary, MPP is the most mature, proven, and widely deployed mechanism for storing and analyzing large amounts of data. So what is an MPP, and why is it special?

An MPP system allocates data into a collection of partitions and assigns them to independent servers using a shared-nothing organization of storage and central processing unit (CPU) resources. A shared-nothing organization of the data means that a given partition of data is "owned" by a single server and there can be no read or write contention for data blocks across multiple servers. This approach delivers superior scalability for large amounts of data because there is no need for locking or other data management coordination between servers that are executing software for reading and writing data into a file system or database. Because there are no coordination costs for database buffer cache coherency or logging across the multiple servers in an MPP environment, it is straightforward to scale this type of architecture to thousands—and even tens of thousands—of servers executing a single (or multiple) workload.

Let's look at an example in the big data world. The nonparallel execution of a query will scan a large table or file one block at a time. If there are a billion records in a database table or file, this could take a very long time. However, idealized parallel execution using a shared-nothing MPP approach with 1000 servers (often referred to as nodes) would reduce the time for execution of the query by a factor of (nearly) 1000. The billion records of data would be divided up among the 1000 servers in the MPP system (usually through use of a hashing algorithm against a DBA-assigned partitioning key for each file or table). Each server would then execute in parallel against the (roughly) one million rows assigned to it (Figure 20.2).

There are two critical success factors for obtaining linear scalability in a shared-nothing MPP system for data management:

1. Data must be divided up evenly across the many servers in the MPP because all servers must wait for the slowest one (or one with the most work) to finish.
2. Assembly of results from across the multiple servers must be done as much in parallel as possible.

Dividing data evenly across the MPP servers is critical because the time that it takes to execute a query will be dictated by the slowest server (or the one with the most work). All servers must finish their portion of the work in order for a query to complete. If any server is lagging behind because it has more data to process than the others, the overall query execution time can suffer dramatically. Applying a hashing algorithm to the partitioning key for each record in a file allows placement of data across servers in an MPP system in a relatively balanced way so as to ensure efficiency in parallel processing. Studies have shown that scale-out parallelism with many commodity servers working together will outperform the scale-up computer systems using traditional symmetric multiprocessing (SMP) architectures using a shared memory or nonuniform memory access (NUMA) implementation [6]. However, since there are

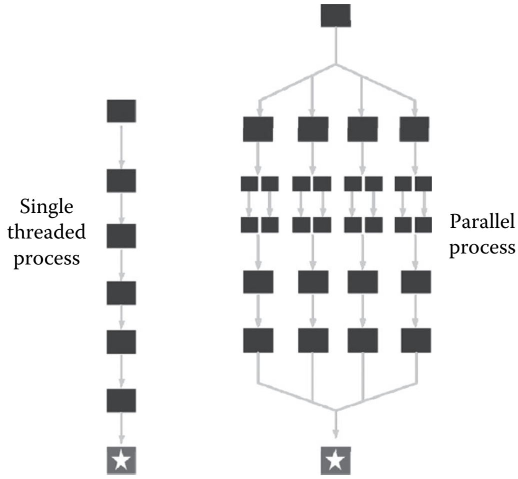

FIGURE 20.2 Serial query execution versus MPP query execution.

many hardware and software components in a large MPP system, failures are inevitable. MPP systems are architected with built-in redundancy so that data is stored in more than one location to make recovery easy in cases where there is a hardware or software error associated with a node.

20.3.2 Cloud Computing

As with any new and emerging technology, there are conflicting definitions describing the concept of cloud computing. We will consider two that serve as a solid foundation for our discussion. The first comes from a McKinsey and Company paper published in 2009 [7]. The paper listed three criteria for a cloud environment:

1. Enterprises incur no infrastructure or capital costs, only operational costs. Those operational costs will be incurred on a pay-per-use basis with no contractual obligations.
2. Capacity can be scaled up or down dynamically and immediately. This differentiates clouds from traditional hosting service providers where there may have been limits placed on scaling.
3. The underlying hardware can be anywhere geographically. The architectural specifics are abstracted from the user. In addition, the hardware will run in multi-tenancy mode where multiple users from multiple organizations can be accessing the exact same infrastructure simultaneously.

A key concept behind this definition is that cloud infrastructure takes away concern for resource constraints. Users can get whatever they need whenever they need it. They will get charged, of course, but only for what they use. No more fighting with system administrators over resources.

Another definition comes from the National Institute of Standards and Technology (NIST), which is a division of the U.S. Department of Commerce. NIST lists five essential characteristics of a cloud environment [8]:

1. On-demand self-service
2. Broad network access
3. Resource pooling
4. Rapid elasticity
5. Measured service

Each of those criteria has to come into play. The similarities between the McKinsey definition and the NIST definition are easy to see. You can learn more about the work the NIST has done on the cloud on their website [9]. There are two primary types of cloud environments: (1) public clouds and (2) private clouds.

20.3.2.1 Public Clouds

Public clouds, such as Amazon's EC2, have gotten the most attention in the marketplace and align most closely to the definitions provided earlier. With a public cloud, users are basically "renting" access to a large farm of servers and storage. Data is loaded onto a host system and resources are allocated as required to process the data. Both open source (e.g., Hadoop) and commercial (e.g., Teradata) software packages are available in the public cloud for the purpose of big data processing. Users get charged according to their usage but have no capital costs associated with hardware or software acquisition.

Because processing capacity is consumed as needed from a huge pool of resources, it is not necessary to buy a system sized to handle the maximum capacity ever required for big data analytics. The public cloud approach avoids the situation where nonuniform demand for computation creates the need to buy large amounts of capacity to handle spikes in demand when most of the time much less capacity is required (resulting in underutilized resources). When there are bursts where lots of processing is needed, it is possible to acquire incremental resources from the public cloud without actually owning those resources. The user is simply billed for the extra resources on a pay-for-use basis.

A huge advantage of cloud computing for big data analytics is fast ramp up because end users are leveraging preexisting infrastructure with little to no setup time. Once granted access to the cloud environment, users load their data and start analyzing. It is easy to share data with others regardless of their geographic location since a public cloud is accessible over the Internet and is outside of corporate firewalls. Anyone can be given permission to log on to the environment created. Of course, the advantage of sharing needs to be weighed against the potential security exposures associated with public cloud infrastructure.

As a result of the scale of resources available in a large public cloud infrastructure, computing throughput is generally quite scalable and relatively high performance. But, like any shared infrastructure, there can be peak periods of demand when performance cannot be guaranteed. One solution to this issue is "reserve" resources in a public cloud through use of virtual private cloud allocation. By "leasing" an allocation of resources from the public cloud, a user can be protected from variations in demand for resources during the leasing period.

20.3.2.2 Private Clouds

A private cloud has many of the same features as a public cloud, but it is owned exclusively by one organization and typically housed behind a corporate firewall. An important implication of the private cloud approach is that the owning organization incurs the capital costs of acquiring the hardware and software for enabling the cloud. A private cloud serves the same function as a public cloud but just for the people or teams within a given organization (see Figure 20.3 for an illustration of a public versus a private cloud).

One huge advantage of a private cloud is that the owning organization will have complete control over the data and system security. Data is not being deployed outside the corporate firewall so there is no concern about violating policies (or government regulations) related to geographic placement of data or reliance on security implementations put in place by third parties. The data is at no more risk than it is on any other internal system.

A significant downside of a private cloud is that it is necessary to purchase and own the entire cloud infrastructure before allocating it out to users. This takes time and money. Capital outlay this year will increase this year's expense relative to a public cloud. In the years that follow, there will generally be a lower cost for allocating resources from the (already paid for) private cloud than if resources are acquired from a public cloud.

The overall total cost of ownership will depend on economies of scale and efficiency of an organization's data center operations. Private cloud computing rarely makes sense for a small organization

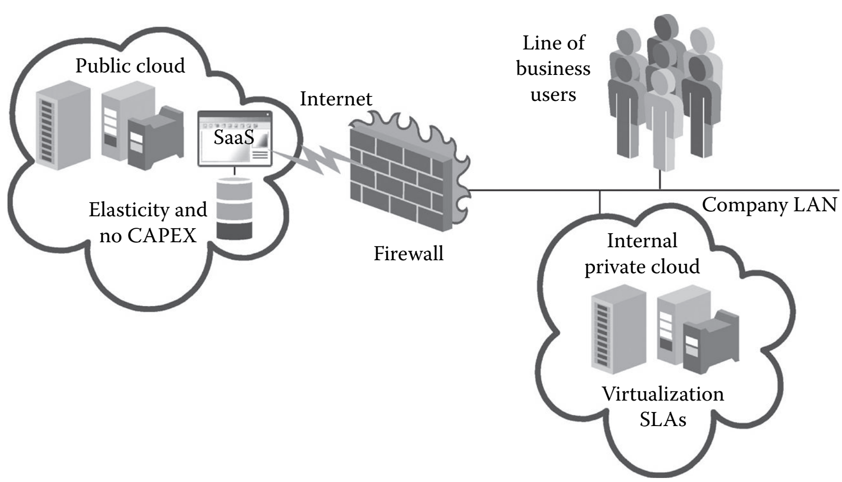

FIGURE 20.3 Public cloud versus private cloud.

because lack of buying power and lack of scale for creating world class data center capabilities means that public cloud computing will almost always be lower total cost of ownership.

However, for large organizations with world class data center operational capability, it is likely that private cloud computing will be more cost effective than public cloud computing. Organizations such as eBay, Facebook, Yahoo!, Google, and many others use private cloud computing for their big data processing. In the long run, if a lot of big data analysts will be using a cloud environment, it can be much cheaper to have a private cloud with good workload management than pay fees for accessing resources delivered via a public cloud. However, the initial capital outlay and setup will cause higher costs in the short term when implementing a private could. Over time, the balance will shift. This is especially true if large volumes of data would need to have been moved from enterprise systems into a public cloud (versus localized movement within the data centers of the enterprise).

20.3.3 MapReduce

MapReduce is a parallel programming framework popularized by Google to simplify data processing across massive data sets [10,11]. MapReduce consists of two primary processes that a programmer builds: the "map" steps for structuring and assigning data across the parallel streams of processing and the "reduce" steps for computation and aggregation. The MapReduce framework coordinates the execution of the map and reduce logic in parallel across a set of servers in an MPP environment. The logic for mapping and reducing can be written in traditional programming languages, such as Java, C++, Perl, and Python.

Assume that we have 20 TB of data and 20 MapReduce server nodes on which to run our analysis. The first step is to distribute 1 TB to each of the 20 nodes using a simple file copy process. The data should be distributed prior to the MapReduce process being started. Data is in a file of some format determined by the user. There is no standard format like in a relational database. Next, the programmer submits two programs to the scheduler. One is a map program; the other is the reduce program. In this two-step processing, the map program finds the data on disk and executes the mapping logic. This occurs independently on each of the 20 servers in our example. The results of the map step are then passed to the reduce process to summarize and aggregate the final answers (see Figure 20.4 for a visual description of the MapReduce process). MapReduce programming breaks an analytic job into many tasks and runs them in parallel.

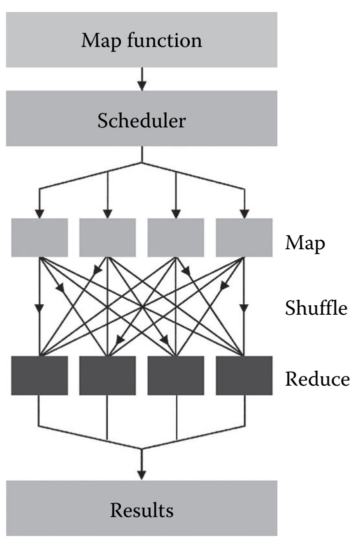

FIGURE 20.4 The MapReduce process.

20.3.3.1 Scheduler

Let's look at an example where an organization has a large volume of text flowing in from online customer service chats taking place on its website. This is the classic example to show how the MapReduce programming framework parallelizes large-scale data processing. In this example, text paragraphs are provided as input. A programmer creates a map step to parse out each word present in the chat text. In this example, the map function will simply find each word, parse it out of its paragraph, and associate a count of one with it. The end result of the map step is a set of value pairs such as "<my, 1>," "<product, 1>," "<broke, 1>." When each worker task is done executing the map step, it lets the scheduler know.

Once the map step is complete, the reduce step is started. At this point, the goal is to figure out how many times each word appeared. What happens next is called shuffling. During shuffling the answers from the map steps are distributed through hashing so that the same words end up on the same reduce task. For example, in a simple situation, there would be 26 reduce tasks so that all the words beginning with A go to one task, all the Bs go to another, all the Cs go to another, and so on.

The reduce step will simply get the count by word. Based on our example, the process will end up with "<my, 10>," "<product, 25>," "<broke, 20>," where the numbers represent how many times the word was found. There would be 26 files emitted (one for each reduce node) with sorted counts by word. Note that another process is needed to combine the 26 output files. Multiple MapReduce processes are typically required to get to a final answer set.

Once the word counts are computed, the results can be fed into an analysis. The frequency of certain product names can be identified. The frequency of words like "broken" or "angry" can be identified. The point is that a text stream that was "unstructured" has been structured in a fashion that allows it to be easily analyzed. The use of MapReduce is often a starting point in this way. The output of MapReduce can be an input to another analysis process (Figure 20.5).

There can be thousands of map and reduce tasks running across thousands of machines. When there are large volume streams of data and the processing that needs to be executed against the data can be partitioned into separate streams, the performance of the MapReduce programming framework will be very scalable. If one worker does not need to know what is happening with another worker to execute effectively, it is possible to achieve linear scalability in the parallel processing of large data sets. The essence of the MapReduce framework is to allow many servers to share the burden of working through a large amount of data. When the logic required can be run independently on different subsets of the data, the shared-nothing nature of the MapReduce framework makes processing very scalable.

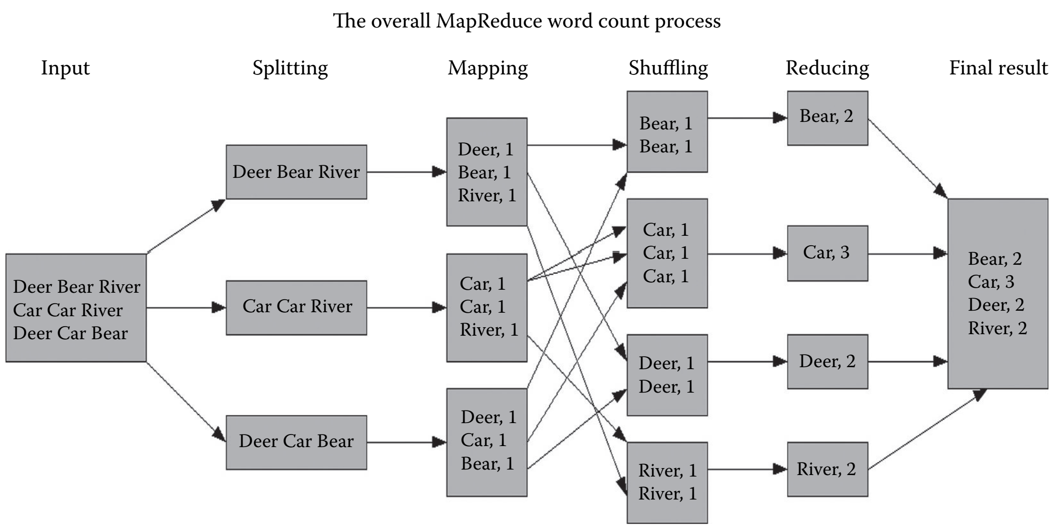

FIGURE 20.5 Simple word count with MapReduce.

In our example, each word can be parsed by itself, and the contents of the other words are irrelevant for a given map worker task.

Recall that well-designed MPP systems spread data out across nodes that can then be queried with efficient use of parallelism. The MapReduce framework makes use of a technique called "data parallelism" whereby each worker runs the same code against its portion of the data. However, the parallel workers are independent and do not interact or even have knowledge of each other. If there is a steady stream of web logs coming in, chunks of data would be allocated to the various workers so that they can process in parallel. A simple method would be a round robin procedure where chunks of web logs are passed to nodes sequentially over and over. Hashing algorithms are also a common method for distributing data across workers. In this case, records are passed to workers based on a mathematical formula so that records with the same partitioning key get sent to the same worker. For example, hashing on customer ID will send all records for a given customer to the same worker. The hashing method can dramatically increase efficiency if analysis by customer ID is planned.

MapReduce offers some significant advantages for big data analytics that go beyond what relational database management systems provide. First, for data that is nontraditional (e.g., not in record format), the lack of imposed data structure from the programming model means that there is a lot more flexibility in handling non-relational data such as web logs, text, graphs, and rich media. Structure can be overlaid on top of file system data at the time of analytics rather than at the time of loading. Thus, MapReduce provides a quite suitable programming framework to handle analytics with multi-structured data. A polymorphic file system is capable of efficiently storing data in many different structures and is a foundational component of a big data processing environment.

Second, MapReduce facilitates the use of programming models that extend beyond the traditional SQL processing capabilities available on an American National Standards Institute (ANSI) standard relational database management system. As a set processing language, there are certain capabilities that are not efficiently executed within SQL. For example, time series analysis is generally quite awkward to express in SQL because set processing is not well aligned to ordered analytics. Market basket analytics or execution of graph algorithms have been implemented on top of relational databases for many years, but MapReduce offers the opportunity to simplify and improve performance on these types of more sophisticated analytics.

Hadoop is the most widely used open source implementation of the MapReduce programming framework and is used widely in the dot-com industry. Hadoop is available at no cost via the Apache open source project. Hadoop was originally started as an open source search engine project by the name of "Nutch" in 2004 and was later spun off and adopted by Yahoo! in 2006. The principle design goals for Hadoop were centered around providing extreme scalability for batch processing of analytics on top large volumes of (unstructured) text data from web pages and their links.

The NoSQL movement within the big data analytics community will sometimes position traditional relational databases and the SQL programming language as obsolete. The idea is that MapReduce on top of the Hadoop Distributed File System (HDFS) can do everything that SQL on top of a relational database can do—and more—so why not replace all Relational Database Management System (RDBMS) implementations with Hadoop? The reality is not quite so simple.

There is quite a bit of controversy surrounding the relative strengths and weaknesses of Hadoop versus relational databases [12,13]. Relational databases are far more mature than the Hadoop environment in the areas of optimizer technology, schema abstraction, security, indexes, interactive query and reporting tools, performance management, and many other areas. The reality is that Hadoop is largely deployed in highly technical environments where computer scientists are directly involved in analysis of big data. In order to get wider adoption of big data analytics, enterprises have a strong desire to deploy technologies that can be used by data scientists who are not necessarily computer programmers. The open source community has a number of initiatives to close the usability gap that exists with Hadoop deployments through use of higher level data access languages such as Pig and Hive.

At the same time, commercial vendors have begun extending traditional relational database products with MapReduce capabilities. Major vendors in the analytics marketplace such as EMC, IBM, Oracle,

and Teradata have either already deployed relational databases with MapReduce extensions or have initiatives along these lines well underway. We would propose that a more rational realization of the NoSQL movement would result in "Not Only" SQL deployments. Sometimes SQL is a very appropriate language for big data analytics and sometimes something more is required. MapReduce is an important extension to the analytic capabilities of traditional databases that allows much more effective big data processing than SQL on its own.

The open source implementation of Hadoop makes it a very attractive storage area for capturing large volumes of data. The use of commodity storage and Just a Bunch of Disk (JBOD) storage along with zero-cost software licensing creates a low total cost of ownership value proposition. Increasingly, organizations are using Hadoop to stage high-volume data for analytic purposes. Preprocessing and filtering big data using batch jobs in preparation for discovery analytics is performed on the Hadoop staging platform. The data prepared on Hadoop is then loaded into next-generation relational databases implemented with MapReduce extensions to the SQL programming language. The extended relational platforms are better suited for efficient execution of complex workloads and providing interactive analytics with big data, while the Hadoop platform provides excellent total cost of ownership characteristics for large-scale data storage and more simplistic scanning, filtering, and aggregation of data.

20.4 Conclusions

The tools and technologies associated with big data processing are still emerging in their capabilities and adoption. Using Geoffrey Moore's framework for new technology introduction into the marketplace [14], we can observe that big data analytics is well past the incubation and early adopters stages and is just at the cusp of being embraced by the early majority pragmatists within the Fortune 1000.

The early hype associated with big data technologies that implied that enterprise data warehouse infrastructures were in imminent danger of being replaced by the new-generation NoSQL tools for all analytics was clearly overstated. However, it is clear that there is high value-added analytic capability provided by these tools. In the early days, big data ecosystems primarily consisted of the MapReduce programming model implemented on top of the HDFS. The ecosystem has evolved significantly over the past several years to include better support for management and administration (ZooKeeper, Karmasphere, Cloudera), query scripting and programming language support (Hive, Pig, Jaql, Mahout), query tools (Pentaho, Datameer), data sourcing (chuckwa), workflow optimization and scheduling (Oozie), metadata management (Hortonworks), and so on.

Core investments, being made by both the open source community and commercial vendors, are targeted at making the big data analytics platforms more scalable, reliable, and performant. Moreover, integration with other data platforms (relational databases, data integration tools, data mining tools, etc.) is addressing mainstream market requirements for adoption of big data technologies. It is clear that big data technologies are here to stay and that the open source and commercial communities will continue to evolve capabilities in this area. Eventually, like object technologies in the late part of the previous millennium, big data technologies will become part of the standard capabilities expected of all participants in the area of enterprise data management.

Governance of Organizational Data and Information

Walid el Abed
Global Data Excellence

Paul Brillant Feuto Njonko
University of Franche-Comté

21.1 Introduction to the Notion of Governance

Before diving into the specific case of data governance (DG), it is important to outline the notion of governance in the broader sense because DG is but one form of governance. A governance program is used to define the decision-making processes and authority around a specific domain. In other words, a governance program is about deciding how to decide in order to be able to handle complex situations or issues in the future in the most controlled and efficient way possible.*

Over the past decade, corporate governance has been defined as a set of relationships between a company's management, its board, its shareholders, and other stakeholders that provide a structure for determining organizational objectives and monitoring performance, thereby ensuring that corporate objectives are attained (Khatri and Brown, 2010). Under this broad umbrella that sets enterprise-wide policies and defined standards, it is necessary to implement different governance areas to achieve the goal of a good and responsible corporate governance structure. Weill and Ross propose a framework

* http://www.element61.be/e/resourc-detail.asp?ResourceId=6

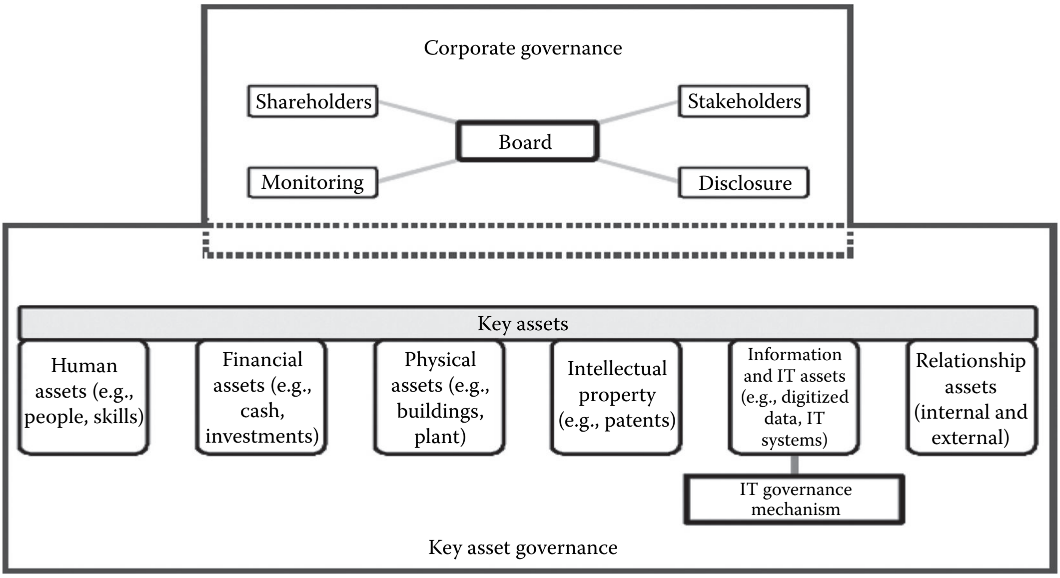

FIGURE 21.1 Corporate and key asset governance.

for linking corporate governance with six key assets of a company, which are the basis of generating business value and for realizing the company's strategies (Weill and Ross, 2004). Figure 21.1 is based on Weill and Ross' understanding of corporate and key asset governance and depicts the dependencies between these areas.

Since information technology (IT) is an essential part within a company's structure, quality management has to ensure corporate governance compliance of its IT systems. Thus, the discipline IT governance has been established and concentrates its activities on handling of technology and its usage within the company. For Weill and Ross, the IT governance has the goals in specification of decision rights and accountability frameworks to encourage a desirable behavior in the IT usage. In addressing of the following three questions, effective IT governance will be set up:

- What decisions regarding the use of IT must be made?
- Who should make these decisions?
- What are the characteristics of the decision and monitoring processes?

In this context, IT governance relates to the management of IT life cycles and IT portfolio management. This scope does not include the information itself, its value, and its life cycle management. The necessary examination of the relevance and the value chain of information should be part of an information and DG. Unlike Weill and Ross, many researchers emphasize that data and information governance are not a subset of IT governance. Accomplishing corporate data quality requires close collaboration among IT and business professionals who understand the data and its business purpose; in addition, both have to follow corporate governance principles. DG broadens the scope of IT governance by considering data quality aspects and processes especially defined to clarify the life cycle of data. According to Khatri and Brown, IT assets refers to technologies (computers, communication, and databases) that help support the automation of well-defined tasks, while information assets (or data) are defined as facts having value or potential value that are documented. Data Governance Institute (DGI)* makes the difference between IT and DG by analogy with the plumbing system: IT is

* http://www.datagovernance.com

like the pipes and pumps and storage tanks in a plumbing system. Data (information) are like the water flowing through those pipes.

21.1.1 Scope of Data (Information) Governance in the Overall Corporate Governance

DG is an essential part of an overall corporate governance strategy as an equal subdiscipline alongside IT governance. DG is a cross-organization and organization-wide initiative that requires that any barriers between IT and business are brought down and that they are replaced with well-defined roles and responsibilities for both the business areas and the technical areas of the organization. The "*who does what and when*" question is much more important than the "*where*" question. Its goal is to govern and manage data and information by organizing the proper usage of data and defining the responsibilities for data and respective data quality.

Furthermore, DG should be clearly distinguished from data management and data quality management (DQM) (Brown and Grant, 2005) because the most common definitional mistake companies make is to use DG synonymously with data management. DG is the decision rights and policy making for corporate data, while data management is the tactical execution of those policies. In other words, DG is not about what specific decisions are made. That is management. Rather, it is about systematically determining who makes each type of decision (a decision right), who has input to a decision (an input right), and how these people (or groups) are held accountable for their role. DG requires a profound cultural change demanding leadership, authority, control, and allocation of resources. DG is the responsibility of the board of directors and executive management and more focused on corporate environment and strategic directions, including other areas beyond DQM, such as Data Security and Privacy and Information Life-Cycle Management (Lucas, 2010). With DG, organizations are able to implement corporate-wide accountabilities for DQM, encompassing professionals from both business and IT units. Figure 21.2, extended from Brown and Grant (2005), illustrates the scope of DG in the corporate governance and the position between governance and management.

In this chapter, in line with most data or information governance publications, we have used synonymously the terms "data" and "information" although they may have different meanings in some contexts.

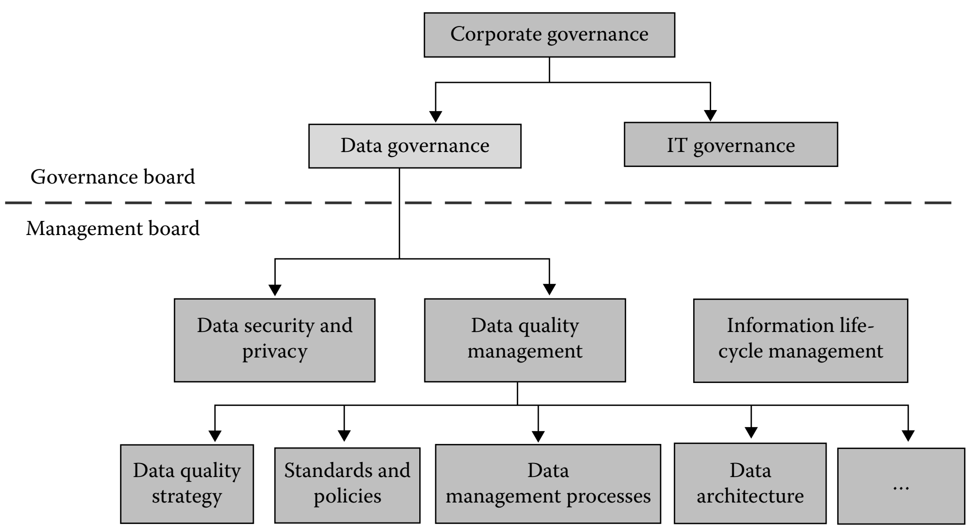

FIGURE 21.2 Position of DG in the corporate governance and difference between governance and management.

21.2 Data Governance

21.2.1 Introduction

Nowadays, volumes of data are steadily growing up, and organizations are seeking new ways to exploit their data as enterprise assets in order to fuel their growth. However, data of high quality are a prerequisite for fulfilling these objectives. Moreover, understanding how the data are being used throughout the business is vital for ensuring that legal, ethical, and policy-based requirements are met. Over the past few years, many organizations adopted DQM focusing on collecting, organizing, storing, processing, and presenting high-quality data. The organizational issues that must be addressed, such as defining accountabilities, managing expectation and compliance, avoiding scope creep, and handling political issues, push DQM into an area of conflict between business and IT. On the one hand, DQM has to provide many stakeholders (e.g., CEOs, sales, controlling, procurement, IT, business units, customers, public authorities) with high-quality corporate data. On the other hand, these stakeholders have different interests (e.g., local/regional/company-wide differences), which do not necessarily accumulate to the best achievable result for the company as a whole. Because of these particularities of DQM, large multi-business companies are likely to have difficulties with institutionalizing DQM, that is, defining accountabilities, assigning people accountable for DQM within the organizational structure, and enforcing DQM mandates throughout the company.

DG addresses these particular issues by implementing corporate-wide accountabilities for DQM that encompass professionals from both business and IT. It specifies the framework for decision rights and accountabilities to encourage desirable behavior in the use of data. It establishes organization-wide guidelines and standards for DQM and assures compliance with corporate strategy and laws governing data.

21.2.2 Definition

DG is an emerging discipline with an evolving definition. There are varying definitions of DG because each practitioner tailors DG to its needs and abilities. Here are some definitions that cover almost all the components and goals of DG:

> Data Governance is a system of decision rights and accountabilities for information-related processes, executed according to agreed-upon models which describe who can take what actions with what information, and when, under what circumstances, using what methods.
>
> *The Data Governance Institute**

> Data governance is a quality control discipline for adding new rigor and discipline to the process of managing, using, improving and protecting organizational information. Effective data governance can enhance the quality, availability and integrity of an [organization's] data by fostering cross-organizational collaboration and structured policy-making
>
> *[IBM, 2007] IBM†*

> Data governance encompasses the people, processes, and information technology required to create a consistent and proper handling of an organization's data across the business enterprise.
>
> *Wikipedia‡*

* http://www.datagovernance.com/adg_data_governance_definition.html (accessed on 31 May 2012)
† http://www.ibm.com/ibm/servicemanagement/us/en/data-governance.html
‡ http://en.wikipedia.org/wiki/Data_governance

The formal orchestration of people, processes, and technology to enable an organization to leverage data as an enterprise asset.

*Customer Data Integration Institute**

All these definitions help us understand the aim and principle of DG, which is to help maximize the value of an organization's data and information assets. In the absence of academic definitions of DG, the working definition used in this chapter was adapted from research on IT governance definition (Weill and Ross, 2004). Thus, DG specifies the framework for decision rights and accountabilities to encourage desirable behavior in the use of data; it encompasses people, policies, procedures, and technologies to enable an organization to leverage data as an enterprise asset.

21.3 Designing Effective Data Governance

The scope of a DG program can be very wide or specific due to the wide variety of backgrounds, motivations, and expectations of DG practitioners. However, a good DG framework ensures that organizational data are formally managed throughout the enterprise as an asset and provides efficient help to the organization to achieve one of the following business drivers:

- Increasing revenue and value
- Lowering costs
- Reducing risks

The following are few descriptions of goals, focus areas, and principles of a DG program. Due to the limited academic research, most of sources come from practitioners on DG, namely, reports by analysts, white papers by consulting companies, vendors, or software manufacturers such as IBM, GDE, Gartner, and Oracle.

21.3.1 Goals of Data Governance

DG is not meant to solve all business or IT problems in an organization. Its goal is to continually produce high-quality data while lowering cost and complexity and supporting risk management and regulatory compliance. The main goals and objectives of DG include the following points:

- Ensure data meets the business needs
- Protect, manage, and develop data as a valued enterprise asset
- Lower the costs of managing data and increase the revenue
- Enable decision making and reduce operational friction
- Train management and staff to adapt common approaches
- Build and enforce conformance to data policies, standards, architecture, and procedures
- Oversee the delivery of data management projects and services
- Manage and resolve data-related issues

21.3.2 Focus of Data Governance

DG frameworks can have a focus on the following areas:

- Policy, standards, and strategy
  The focus on data policies, data standards, and overall data strategies are usually the first step when an organization initiates a DG program. The DG program contributes to the definition of a data strategy and will ensure that consistent policies and standards are used within the

* http://www.tcdii.com

organization. It will steer the creation of new policies and standards and work on the alignment of the existing ones. It will finally monitor that those policies and standards are correctly used with the organization. The main activities of a DG program with a focus on policy, standards, and strategy include the following:
  - Establish, review, approve, and monitor policy
  - Collect, choose, approve, and monitor standards
  - Establish enterprise data strategies
  - Align sets of policies and standards
  - Contribute to business rules
  - Data quality

  The desire to improve the quality and usability of the data is the main driver for this type of DG program. It will set the direction for the data quality program. It will help the organization to define and monitor the quality of its data and help to establish ownership, decision rights, and accountabilities to ensure the quality, integrity, and usability of the data.
- Privacy, compliance, and security
  Depending on the type of the organization, this area might be more or less critical. Companies within the financial services and health-care industries are main adopters of these programs for apparent reasons. In any case, the DG program will help to protect sensitive data and enforce the legal, contractual, or architectural compliance requirements. This will help the organization to control and limit the risks on its data.
- Architecture and integration
  In this domain, the DG program will mainly have a support role by bringing cross-functional attention to integration challenges. It will support initiatives like metadata or MDM programs and help in the definition of architectural policies and standards in order to improve systems integration.
- Data warehousing and business intelligence
  The DG program will help to enforce rules and standards in the various source systems of the organization, which will affect the data warehouses and business intelligence data by providing better quality data. It will also help to clarify and promote the value of the data-related projects in general.
- Management alignment
  The DG program will promote and measure the value of any data-related projects and initiatives toward management. It will help management to align the different initiatives and monitor for them the data-related projects.

Independently of the area of focus, the main activity should be to identify stakeholders, establish decision rights, and clarify accountabilities.

21.3.3 Data Governance Principles

Here are some DG guiding principles that help stakeholders come together to resolve the types of data-related conflicts that are inherent in companies:

- Integrity
  DG participants will practice integrity with their dealings with each other; they will be truthful and forthcoming when discussing drivers, constraints, options, and impacts for data-related decisions.
- Transparency
  DG and stewardship processes will exhibit transparency; it should be clear to all participants and auditors how and when data-related decisions and controls were introduced into the processes.

- Audit ability
  Data-related decisions, processes, and controls subject to DG will be auditable; they will be accompanied by documentation to support compliance-based and operational auditing requirements.
- Accountability
  DG will define accountabilities for cross-functional data-related decisions, processes, and controls.
- Stewardship

DG will define accountabilities for stewardship activities that are the responsibilities of individual contributors, as well as accountabilities for groups of data stewards.

- Checks-and-balances
  DG will define accountabilities in a manner that introduces checks-and-balances between business and technology teams as well as between those who create/collect information, those who manage it, those who use it, and those who introduce standards and compliance requirements.
- Standardization
  DG will introduce and support standardization of enterprise data.
- Change management
  DG will support proactive and reactive change management activities for reference data values and the structure/use of master data and metadata

21.3.4 Benefits of Data Governance

The scope of a DG program can be very wide and needs to be carefully defined in order to provide the benefits the organization is looking for. It also requires specific expertise to implement DG initiatives in a successful way in order to transform the data in the organization into a real asset. Effective DG does not come together all at once, but it is an ongoing process. Before adopting an approach, it is important to assess the current state maturity of the DG capability. Usually, DG program appears in an organization when it reaches a certain maturity level. In that case, it will be necessary to align the existing rules and processes of different groups by using the following iterative approach:

- *Creates and aligns rules*: the governance program will help in the definition of global rules by coordinating and balancing the need of all the stakeholders. It will define the decision process as well as the roles and responsibilities of all the stakeholders involved.
- *Enforces rules and resolves conflicts*: the governance program will then make sure that those rules and processes are used and applied correctly by all the stakeholders. If necessary, they will be enforced. The governance program will also help to prevent or resolve conflicts by providing ongoing services.
- *Provide ongoing services*: the governance program must support the stakeholders in the application of the processes and rules and by identifying any new opportunities to create new rules or to align or adapt existing ones.

Thus, DG program can provide the following benefits to the organization:

- *Reduce costs and complexity*: reduce duplicate data and management processes and reduce likelihood of errors due to the lack of understanding of data or poor-quality data
- *Support compliance*: quicker access to authoritative data in order to achieve compliance goals and avoid cost of noncompliance penalties
- *Support impact analysis*: increase ability to do useful impact analysis (by providing authoritative business rules, system of record information, and data lineage metadata) and provide a capability to assess cross-functional impacts of data-related decisions

- *Help align efforts*: assist business teams to articulate their data-related business rules and requirements to IT, architecture, and data management teams; consider requirements and controls in an integrated fashion; craft cross-functional accountabilities; and develop common data definitions to be used across various systems increasing integration and cross-flow of data
- *Improve data repositories*: provide accountability and support for improving the quality of data in the repository so it can become an authoritative source of information, reduce likelihood of architectural decisions that limit the organization's ability to analyze its information, and increase ability to find authoritative information quickly
- *Improve confidence in data*: increase confidence in data-related decisions and output reports, increase ability to make timely data-related decisions, and increase confidence in data strategy by providing a cross-functional team to weigh in on key decisions

21.3.5 Key Data Governance Components

DG is a cross-organization and organization-wide initiative where people work together to establish standards and enforce policies (or rules) over data processes. Figure 21.3 illustrates that an effective DG involves four key components:

Standards and policies: A key function of DG is to establish standards and enforce policies that guide DG program implementation. These include vision and goals of the organization regarding data standards, data management processes, decision-making jurisdiction, responsibilities, enforcement, and controls. The DG approach should be consistent with the organization's overall mission and stakeholders' expectations. Program goals should be clearly stated, and it should be made clear how these goals address data content needs, what outcomes will be considered a success, and how the progress will be measured. Furthermore, an organization should evaluate the resources required for the long-term sustainability of the program to ensure it can sustain necessary levels of data quality and security over the entire data lifecycle.

Processes: Establishing and enforcing processes around the creation, development, and management of data is the foundation of an effective DG practice. Companies need to define data and data-related business rules, control access to and delivery of data, establish ongoing monitoring and measurement mechanisms, and manage changes to data.

People: Arguably the most important issue that companies must address when launching a DG initiative is how to manage people in order to design the organizational structure. Companies need to define the

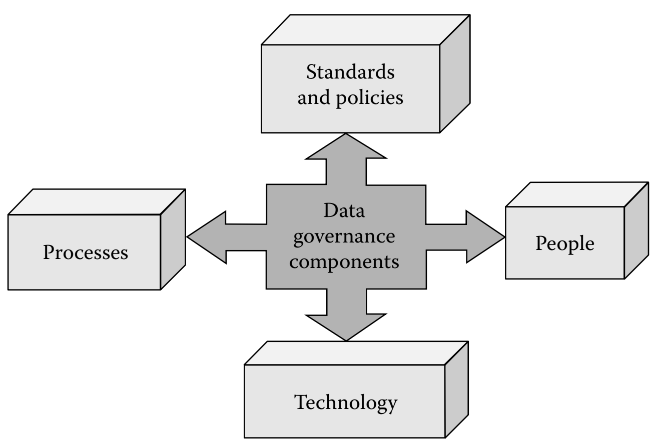

FIGURE 21.3 Four components of DG.

roles and responsibilities within the organization that are accountable for the data. The organization may include several different roles at different levels, involving both business and IT personnel from executive councils to day-to-day implementers, such as data stewards and data analysts. Addressing training and organizational change management issues is also critical if DG programs are to succeed.

Technology: Hypothetically, companies could embark on a DG initiative without an underlying technology infrastructure. Indeed, many organizations launch their initial DG programs using manual tools (spreadsheets, Word documents, etc.) to capture data definitions and document processes. However, most quickly realize that this kind of manual approach is severely limited. It is difficult to ensure high data quality and availability, security is at risk given the ad hoc nature of the approach, and maintaining detailed documentation is an almost insurmountable task. Indeed, it is nearly impossible to achieve the ultimate goals of DG using a manual approach. Thus, technologies can help automate and scale the development and enforcement of DG standards, policies, and processes.

21.4 State of the Art in Data Governance

Both researchers and practitioners consider DG as a promising approach for companies to improve and maintain the quality of corporate data, which is seen as critical for being able to meet strategic business requirements. It receives increasing interest and has recently been given prominence in many leading conferences, such as The Data Warehousing Institute (TDWI) World Conference, the Excellence Quality Information* Association, the Data Management Association (DAMA) International Symposium, the Data Governance Annual Conference, and the MDM Summit. Recently, Gartner has published the 2012 list of Cool Vendors in Information Governance and MDM (Bill et al. 2012). A recent survey conducted by TDWI highlights the increasing number of organizations investing in formal DG initiatives. Eight percent of the 750 responding organizations have deployed a DG initiative; 17% were in the design or implementation phase and 33% are considering it (Russom, 2006). The results also make clear that DG is an emerging practice area, most governance efforts are in the early phases, and many organizations are still working to build the business case for DG. However, only few scientific findings have been produced so far (Otto, 2010) and academic research on DG is still in its infancy. Research on IT governance is more advanced with the first publication released in 1997 (Wende, 2007) and constitutes the starting point for research in DG.

IT governance follows a more flexible approach for the assignment of accountabilities. Early research distinguished two IT governance models: in centralized models, corporate IT performs all IT functions, whereas in decentralized models, business units' IT performs these tasks. Subsequent research specified more precise IT governance models, acknowledging several IT functions and more than one organizational level. Finally, Weill and Ross (2004) proposed five IT functions, three organizational units, and a distinction between decision and input rights. The combination of these three dimensions resulted in six feasible IT governance models. In conclusion, IT governance research proposes three elements that compose an IT governance model: roles, major decisions areas, and assignment of accountabilities. This idea of IT governance models has been the starting point for research on DG models.

21.4.1 Academic Research on Data Governance

In the academic research area, Wende has proposed a model for DG similar to IT governance models to document the company-specific decision-making framework of DQM (Wende, 2007). His model, shown in Table 21.1, outlines the three components of such a framework, namely, DQM roles, decision areas, and responsibilities. For the components, he identifies typical data quality roles and decision areas and proposes a method to assign responsibilities. The approach respects the fact that each company needs a specific DG configuration.

…						

Source: Wende, K., A model for data governance—Organizing accountabilities for data quality management, In *18th Australasian Conference on Information Systems*, 2007.
R: Responsible; A: Accountable; C: Consulted; I: Informed

The three components are arranged in a matrix, the columns of the matrix indicate the roles in DQM, the rows of the matrix identify the key decision areas and main activities, and the cells of the matrix are filled with the responsibilities, that is, they specify degrees of authority between roles and decision areas. A company outlines its individual DG configuration by defining data quality roles and decision areas and responsibilities and by subsequently arranging the components into the model. This configuration is unique for each company. However, this model only focused on the DQM accountability aspect of DG and did not address other areas of DG such as compliance and privacy. Similarly, Khatri and Brown (2010) proposed a framework, which inherits an existing IT governance framework with a set of five data decision domains. For each decision domain, they create a DG matrix, which can be used by practitioners to design their DG model. The framework places special interests in data principles and data life cycle in addition to data quality, data access, and metadata. Boris Otto has developed a morphology of DG organization for answering the question: What are the aspects that need to be considered in order to capture the entirety of DG organization? Based on deductive analysis, the morphology constitutes an analytic theory, that is, it identifies and structures the basic concepts of DG organization (Otto, 2010).

Figure 21.4 describes the morphology of DG organization developed in Otto's research and identifies 28 organizational dimensions.

The first organizational dimension (1) relates to an organization's goals divided into formal goals (1A) and functional goals (1B). Whereas the former measure an organization's performance and maintain or raise the value of a company's data assets, the latter refer to the tasks an organization has to fulfill represented by the decision rights defined. The first set of formal goals specified by the morphology comprises a number of business goals or focus areas of DG. The second set of formal goals specified by the morphology is a two-piece set of information system (IS)-/IT-related goals: "increase data quality" and "support IS/IT integration." Functional goals exclusively relate to the decision areas for which DG specifies certain rights and responsibilities.

The second organizational dimension (2) is the organizational structure. It comprises three aspects, namely, the positioning of decision-making power within the hierarchical structure of an organization

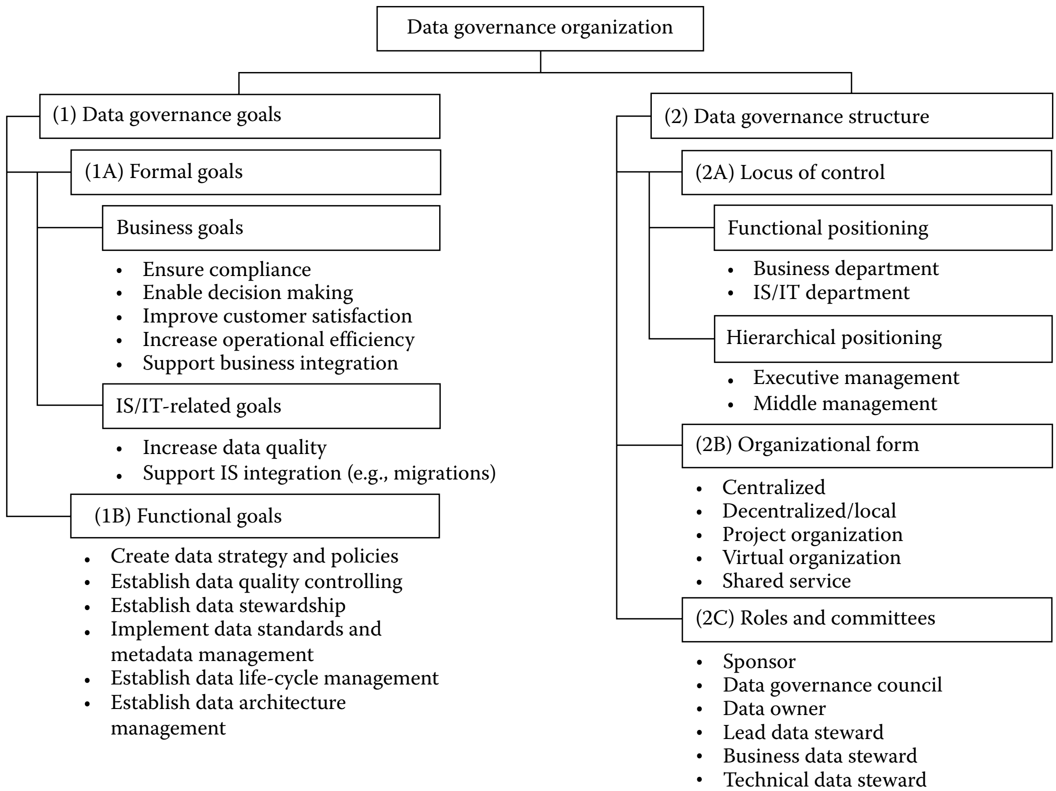

FIGURE 21.4 Morphology of DG organization.

(2A, "locus of control"), the division of labor and the organizational form (2B) resulting from this, and the allocation of tasks to roles and committees (2C).

21.4.2 Data Governance from Practitioners

Numerous DG frameworks and maturity models have been proposed by different organizations with an attempt to provide guidance in designing and developing effective DG approaches. The DG maturity model is a tool to assess your organization's current state of DG awareness and effectiveness. These instruments need to be used judiciously and with regard to particular organizational environments (Chartres, 2012). Each organization will set its own goals and methods based on individual business scenarios, plans, and needs. This leads different organizations to have their own focus on specific aspects of DG. Despite this, they still share some common decision domains, such as data quality at least. The following are a few examples (not comprehensive) of DG frameworks from DG organizations.

21.4.2.1 IBM Data Governance Council Maturity Model

The IBM Data Governance Council is an organization formed by IBM consisting of companies, institutions, and technology solution providers with the stated objective to build consistency and quality control in governance, which will help companies better protect critical data. This common forum, where practitioners explore challenges and solutions, has been instrumental in developing benchmarks, best practices, and guides to successful DG. This is known as the Data Governance Council Maturity Model, shown in Table 21.2. The model has 11 categories, where each category is both a

TABLE 21.2 IBM Data Governance Council Maturity Model

Category		Description
1.	Organizational structures and awareness	Describes the level of mutual responsibility between business and IT, and recognition of the fiduciary responsibility to govern data at different levels of management
2.	Stewardship	Stewardship is a quality control discipline designed to ensure custodial care of data for asset enhancement, risk mitigation, and organizational control
3.	Policy	Policy is the written articulation of desired organizational behavior
4.	Value creation	The process by which data assets are qualified and quantified to enable the business to maximize the value created by data assets
5.	Data risk management and compliance	The methodology by which risks are identified, qualified, quantified, avoided, accepted, mitigated, or transferred out
6.	Information security and privacy	Describes the policies, practices, and controls used by an organization to mitigate risk and protect data assets
7.	Data architecture	The architectural design of structured and unstructured data systems and applications that enable data availability and distribution to appropriate users
8.	Data quality management	Methods to measure, improve, and certify the quality and integrity of production, test, and archival data.
9.	Classification and metadata	The methods and tools used to create common semantic definitions for business and IT terms, data models, types, and repositories. Metadata that bridge human and computer understanding
10.	Information life cycle management	A systematic policy-based approach to information collection, use, retention, and deletion
11.	Audit information, logging and reporting	The organizational processes for monitoring and measuring the data value, risks, and efficacy of governance

starting place for change and a component in a larger plan. The categories are grouped into four major DG domains (IBM, 2007):

1. *Outcomes:* data risk management and compliance; value creation
2. *Enablers:* organizational structures and awareness; policy; stewardship
3. *Core disciplines:* DQM; information life cycle management; information security and privacy
4. *Supporting disciplines:* data architecture; classification and metadata; audit information logging and reporting

21.4.2.2 Data Governance Institute Framework

The DGI framework* provided by the DGI is a logical structure for classifying, organizing, and communicating complex activities involved in making decisions about and taking action on enterprise data. Figure 21.5 describes the architecture of the framework with the 10 universal components:

1. Mission and vision
2. Goals, governance metrics and success measures, and funding strategies

4. Decision rights
5. Accountabilities
6. Controls
7. Data stakeholders
8. A DG office
9. Data stewards
10. Proactive, reactive, and ongoing DG processes

21.4.2.3 Data Excellence Framework

The Data Excellence Framework (DEF) provided by Global Data Excellence (GDE)* describes the methodology, processes, and roles required to generate business value while improving business processes using data quality and business rules (El Abed, 2009b). The framework supports the creation of a new cultural shift focused on data excellence, motivating the broader team and supporting collaboration between the stakeholders. DEF is more than improving data quality and reducing costs; it is about taking a sustainable approach to an organization's data assets to drive value from the data. A key difference about the DEF is that it is focused on generating value in comparison to most initiatives relating to data, which are only focused on reducing costs. The key success of DEF is that it is grounded on both academic research (Feuto and El Abed, 2012) and practical experiences.

* http://www.globaldataexcellence.com

Thus, the data excellence maturity model helps organizations worldwide successfully move from chaos to data excellence stage.

Innovative capabilities in maximizing the value of enterprise data through more effective ways in

1. Aligning and linking business objectives to data management processes via business rules and data quality
2. Measuring and visualizing the business impact of data quality compliance and the value generation of high data quality
3. Organizing and executing sustainable DG processes based on a proven DEF methodology supported by a product solution called the data excellence management system (DEMS)

earned GDE a spot on Gartner's Cool Vendors in Information Governance and MDM for 2012 list (Bill et al. 2012).*

Through the Cool Vendors list, Gartner shines light on companies that use information to enable business outcomes and improve and enrich the meaning and use of master data.

21.5 Data Governance Journey: Application and Business Cases with the Data Excellence Framework

21.5.1 Data Excellence Framework: Govern by Value

As already mentioned in the previous section, DEF describes the methodology, processes, and roles required to measure and govern the business impact of noncompliant data on business activities and the business value generated by fixing the data (El Abed, 2009a,b). The leading concept is the governance by value in order to enable the new paradigm shift as illustrated in Figure 21.6. It supports the creation of a new cultural shift focused on new concept called data excellence, for example, elevating data to

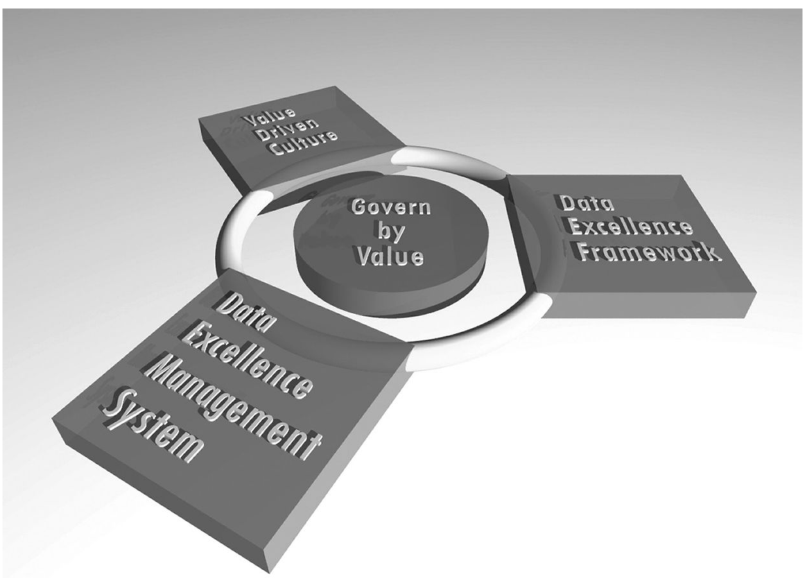

FIGURE 21.6 Govern by value: the new paradigm shift.

* http://www.gartner.com/id=1984515

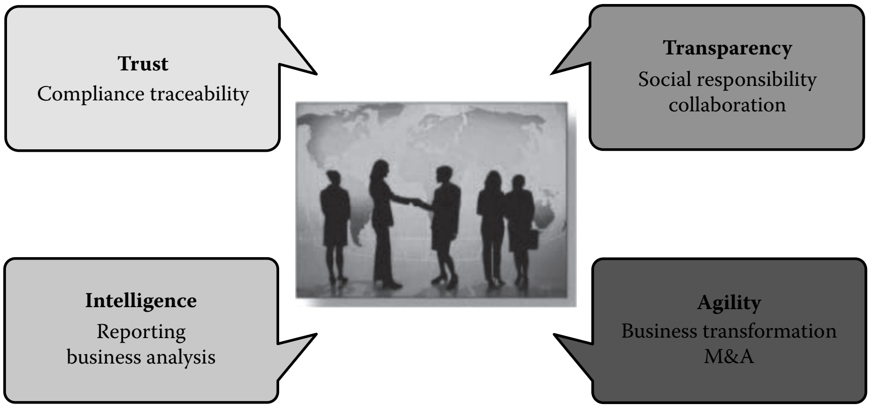

FIGURE 21.7 The value pillars of DEF.

business excellence, motivating the broader team, and supporting collaboration between the business stakeholders, the data management team, and IT. Data excellence arises from the natural evolution of organizations and society in the information age and represents a golden opportunity to enable growth, profit, and flawless execution.

DEF is based on four value pillars (shown in Figure 21.7) that are essential to the survival of any organization or enterprise in the information age: *agility, trust, intelligence*, and *transparency*.

These characteristics are fundamental value pillars to enable business sustainability and support economic growth:

- *Agility* is needed to react to external and internal changes and ensure prompt and successful integration that supports fast business: how fast can you change a process, introduce a new product, or merge a new business.
- *Trust* is associated with the integrity of the data, which induces confidence in enterprise image, brands, and products; empowers business partners, employees, and stakeholders; and ensures legal and compliance traceability.
- *Intelligence* at all levels of the enterprise leads to better and flawless execution, operational efficiency, and accurate financial consolidation based on just-in-time quality data from reporting systems and applications.
- *Transparency* is critical to the organization's performance as it increases visibility and collaboration across and outside the enterprise: not about showing everything but controlling what should be communicated, for example, social responsibility.

These fundamental value pillars result in new ways of working and will lead to maximizing the value and lowering the cost of using data.

21.5.2 Managing Data as a Company Asset

A key difference about the DEF is that it is focused on generating value in comparison to most initiatives related to data that are only focused on reducing costs. Data are an asset, and an asset has a value. The main difference between a tangible asset and the data asset is that the value of data is dynamic and will depend on the context of its usage. Out of the context of usage, the value of data is zero. Moreover, it has a cost, and when the value is not demonstrated, the organization tends to cut this cost.

Price, Cost, and Value

Price and cost are very familiar notions, but value is less understood as a concept. However, value is present in our daily life: We attach sentimental value to our belongings especially when we have to separate from them; we buy goods according to the use or the amount of pleasure they will provide to us. Intuitively, we don't attach value to what is of no use to us although it may have a price or a cost. If you have a fridge filling your needs, it is of no use to buy another one even if there is bargain (e.g., a low price) at the local discount store: therefore, the item has no value for you (except if you think to sell it at a higher price). The price is the monetary amount required to buy an item. It is fixed by the seller and is generally the same for all buyers. It can be negotiated depending on certain factors (volume, delivery mode, etc.). Cost is linked to cost price, which is the total amount of ownership required for the producing and the utilization of an item. Taking the fridge case, its price is the posted price to buy it and cost is the price plus the total expense to run it through its use: electricity, repair, maintenance, etc. Cost is also objective (same for all users).

However, value is subjective and contextual depending on the use we make of it. A bottle of water in the desert can be worth your life (i.e., a lot of money if your life depends on this water), but the same bottle has little value in your daily life as you have plenty of water on the tap. Hence, the value is contextual and instantiate itself at transaction time. Value is therefore subjective as it can vary for different individuals and vary in time for the same person.

Since Frederick Taylor invented his theory of scientific management to improve economic efficiency in the industrial age, enterprises have separated the value generation and the cost management. The former was given to the "business" and the latter to the support functions whose mission is to rationalize and optimize processes (the means). This approach has proved efficient and effective in increasing volumes and reducing costs in an industrial world. However, since we have entered the information age, this separation has disconnected the value creation from the means supporting it and has, in a way, "devaluated" the support functions like IT or data management.

21.5.2.1 What Are the Three Barriers to Manage Data as an Enterprise Asset?

The main barriers are as follows (Figure 21.8):

- *Insufficient alignment between business managers, data management, and IT*: data are noncompliant and are not fit for purpose, and as a result, transactions fail. Despite investing millions in infrastructure and architecture, organizations have not invested in the data. However, data are a key differentiator for organizations when all organizations have similar ERP systems implemented by the same consulting firms. The business, the data management team, and IT are not aligned, resulting in problematic decision outcomes.
- *Inability to demonstrate the business impact of bad data management*: nobody knows the cost of poor data quality and nobody is able to quantify the potential benefit of fixing the data. Worse, nobody knows which data are critical and what the impact of this bad data on the business is. Building a business case to invest in data quality is always difficult, and as a result, the problem still exists. People have lots of anecdotes but find it difficult to quantify their thoughts.

FIGURE 21.8 Barriers to manage data as an asset.

- *Unclear roles and responsibilities to govern data as an asset*: most organizations are struggling to maintain momentum to achieve sustainable business process improvement and flawless execution through data quality improvement processes. This is because nobody feels accountable or responsible for data quality. There is no understanding of the roles or processes needed to sustain high-quality data to fulfill the goals of a DG process. There is no easy way to motivate or sustain the data management team or IT to support the business goals. The DEF provides a method to lower each of these three barriers.

21.5.3 Data Excellence Framework Methodology

The DEF's methodology emphasizes a value-driven approach for enabling business excellence through data excellence. Data excellence becomes an imperative to unlock the enterprise potential and enable sustainable value generation. Thus, data are made visible so that they can become resources for the enterprise to make informed decisions.

In order to lower the three barriers to manage data as a company asset and to maximize the business value of enterprise data, DEF proposes a three-step approach presented at Figure 21.9.

21.5.3.1 Align and Link: Business Excellence Requirements

The purpose here is to align and link business objectives to data management processes via business rules and data quality (see example in Figure 21.10). We introduce the concept of business excellence requirements (BERs): the BER is a prerequisite, business rule, standard, policy, or best practice that business processes, transactions, and data should comply with in order to have the business goals flawlessly executed to generate value. Defining BERs is defining compliance on data quality. The role of the business rules concept implementation enables to action the data quality key performance indicators (KPIs) at the record level and to address the root cause (El Abed, 2008a).

21.5.3.2 Measure and Visualize: DEI and KVI

We measure and visualize the business impact of data quality compliance and the value generation of high data quality. To do so, we use a data excellence index (DEI) measuring the ratio of compliant data and a key value indicator (KVI) measuring the value of compliant data and the value of noncompliant

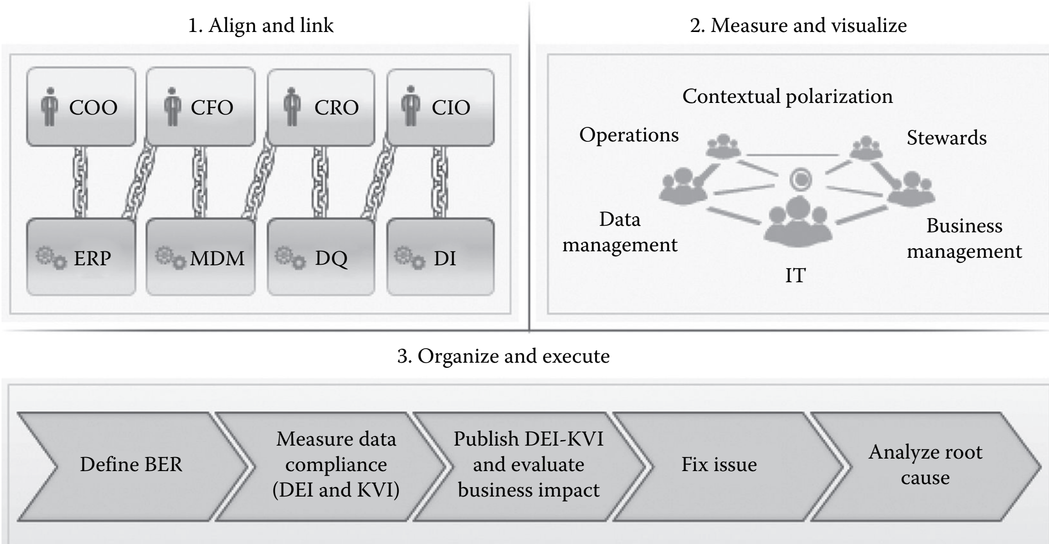

FIGURE 21.9 The three steps to maximize the business value of enterprise data.

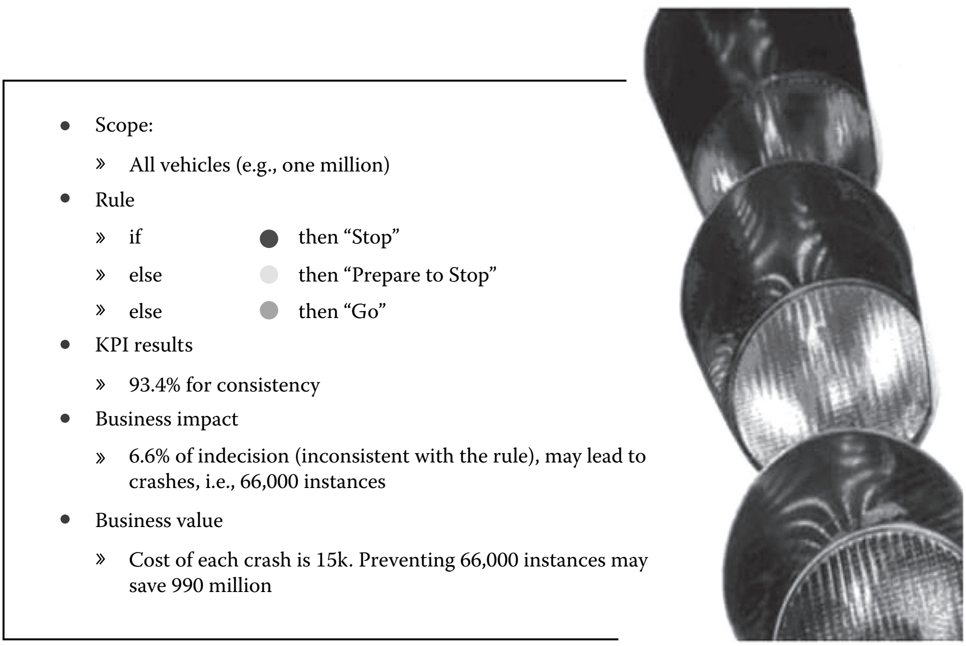

FIGURE 21.10 Example of how a business rule links to business impact and business value.

data (the impact). In compliant and noncompliant data DEIs and KVIs, value and impact can be visualized through different angles (geography, business unit, process, business rule, role, etc.) using the contextual polarization. This helps organizations in

- Providing global visibility of data quality to the whole organization at all levels.
- Publishing the data KPIs monthly on the operation site on the intranet at all levels.

- Presenting the data KPIs at the top management level and at the market management level each month (El Abed, 2008b).
- Measuring the business value through KVIs (aggregated sum and number for real business impact) enables the business users to visualize how DG can help them get there fast (Michellod and El Abed, 2010).

21.5.3.3 Organize and Execute: Accountability and Responsibility

In step 3, the business impact of poor-quality data must be reduced by fixing the wrong data and identifying and analyzing the root causes. In order to manage it efficiently and effectively, new DG must be established including the business, the data management, and IT. The business managers who are accountable and responsible of the value generated in the enterprise will take accountability for the BERs and the associated data, DEIs and KVIs. They will decide which data should be corrected to generate more value by reducing the impact. They will also define accountability and responsibility around the business rules KVIs with business stakeholders (Orazi and Gessler, 2010). Data managers, in charge of the data management of the BER-associated data, will take responsibility for these data. They will correct data and optimize processes upon business order. IT will provide and support the systems necessary to manage these data. The Global DEF is modifying the role of the MDM manager, giving the role higher visibility and strategic positioning (Delez, 2010). The higher the person is in the hierarchy, the faster he or she understands how powerful and useful the DEF to achieve their objectives, and people can no longer question the importance of data errors—with the KVIs, the business impact and value generation are now obvious (Michellod and El Abed, 2010).

In order to facilitate the implementation of this three-step approach, a process including eight questions is provided as shown in Figure 21.11. A simplified view of DEMS, which is a collaborative and evolutionary system to fully support the implementation of DEF capabilities, is presented in Figure 21.12.

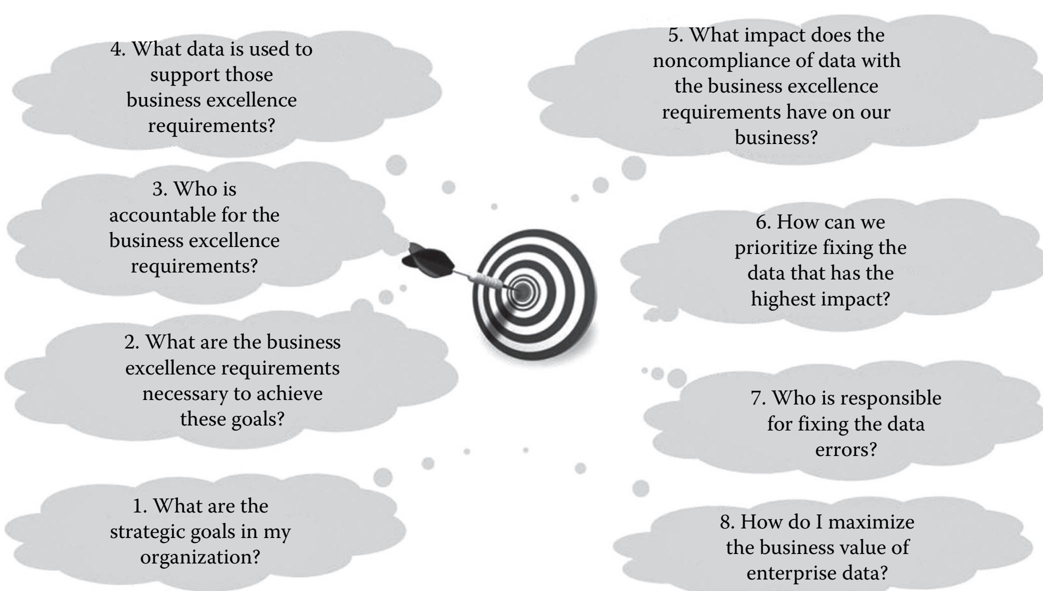

FIGURE 21.11 The eight critical questions linking your business and your data.

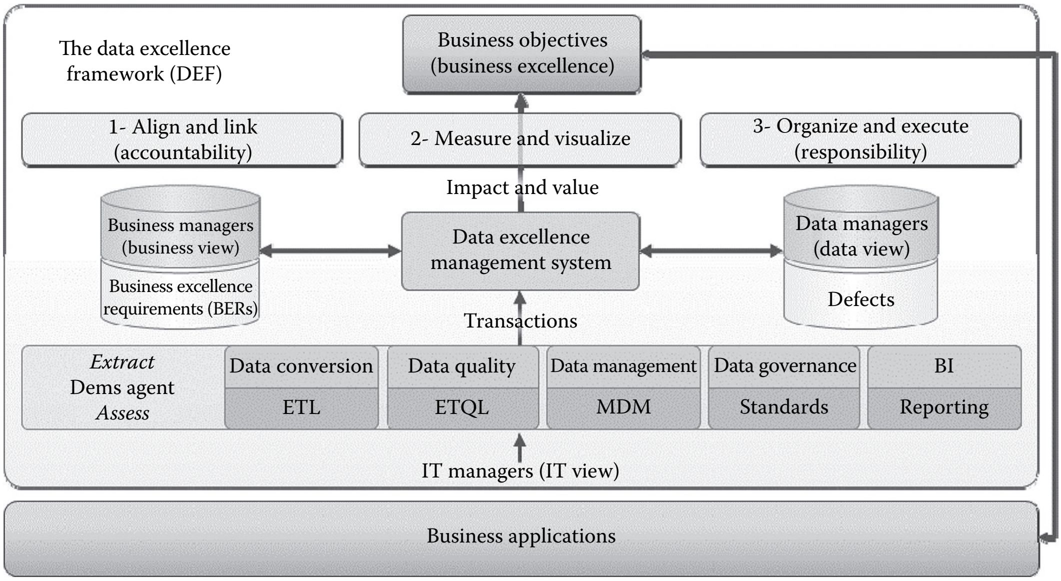

FIGURE 21.12 DEMS.

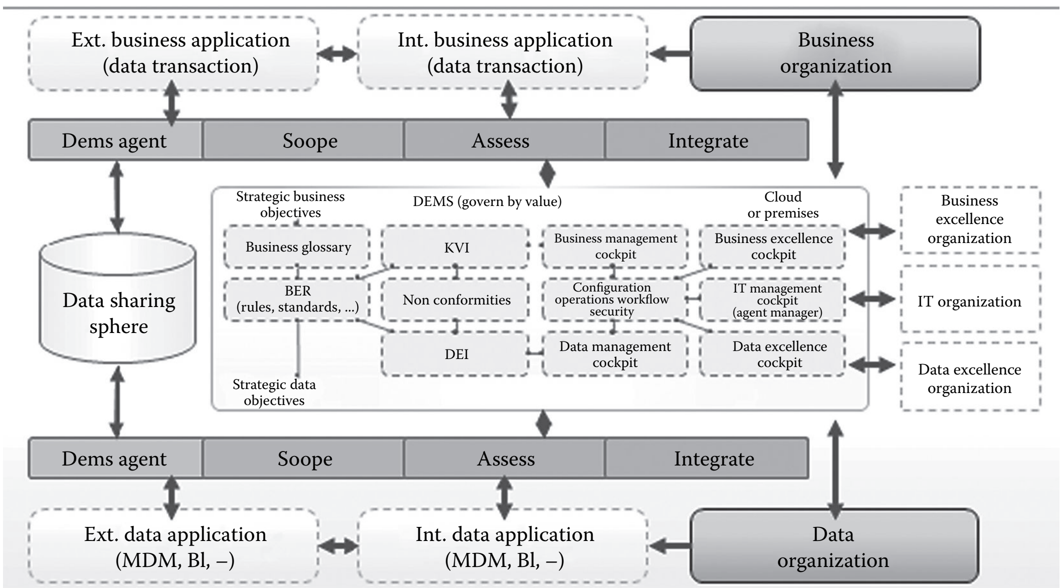

FIGURE 21.13 DEMS in the enterprise environment.

Figure 21.12 shows the general architecture of DEMS. However, it does not show how DEMS could be integrated in the enterprise environment. Thus, Figure 21.13 provides a detailed functional architecture of DEMS in the enterprise environment. It makes a clear difference between the master data and the transactional data and presents the data sharing sphere and how it can be implemented and governed.

21.5.4 Business Case

We are now going to illustrate the application of the DEF through a simple business case in financial institution chosen from many possibilities: the allocation of loans by a bank to its customers.

Business Case: Allocation of Loans by a Bank to Its Customers

SmartBank is a retail bank who has two brands: BankA and BankB both operating in two regions, West and East.

Strategic goal: to govern the risk linked to the distribution of loans and maximize their value

Scope: all loan applications

Data: customer data

21.5.4.1 Scope

The scope is the set of data objects and business processes that are defined before starting the exercise. This scope is dynamic and can be extended or reduced according to the business critical requirements.

In this example, the scope is the set of loan applications at BankA and BankB in the East and West regions. This scope could be reduced to BankA in the East region or extended to another brand of SmartBank (BankC) or to all regions.

The business process is the loan validation process and data objects are the loans (transactions) and customer data.

21.5.4.2 Business Excellence Requirements

The BERs, a unique value proposition representing the backbone of the DEF, are a prerequisite business rule, standard, policy, or best practice that business processes, transactions, and data should comply with in order to have the business goals flawlessly executed to generate value.

21.5.4.2.1 Example

In this example, the SmartBank loan business manager has defined three BERs for the loan allocation process:

BER 1: "a customer record of default must be provided for any loan application if the amount is over or equal to 10000€." This record states whether the customer had defaulted on a loan repayment in the past.

BER 2: "no loan is granted to minor customers (e.g., under 18)."

BER 3: "each application must be accompanied with a payslip."

It is the responsibility of each branch account manager to make sure that any loan application is compliant with these three BERs before they are examined by the SmartBank loan committee for approval.

21.5.4.3 Data Excellence Index

21.5.4.3.1 Definition and Role

The DEI is the instrument used to measure the compliance of data records with the BERs. It consists of the following:

- The percentage of data records compliant with a collection of BERs
- The list of compliant and noncompliant records

Each data record impacts the DEI (positively or negatively) only once regardless of the number of BER applied to this record.

The DEI results are used to evaluate the value and impact of data on business processes and transactions. The BER concept makes the DEI actionable at the record level allowing finest root cause analysis and surgical DG.

21.5.4.3.2 Example

In this example, the three BERs have to be applied to the two data objects: the loans and the clients included in the case scope (see preceding text). The extraction of data from BankA and BankB ISs yields the following data:

Records	Région	Bank	Account Manager	Customer Name	Customer First Name	Age	Income	Loan Amount	Pay slip Provided	Default Record Provided
Record 1	East	BankA	Claus French	Dupont	Jean	75	30,000	9,000	No	
Record 2	East	BankB	Claus French	Proust	Marcel	50	40,000	11,000	Yes	Yes
Record 3	East	BankA	Julian Wood	Flaubert	Gustave	35	25,000	11,000	Yes	Yes
Record 4	East	BankB	Gilbert Sullivan	Monet	Claude		22,000	5,000	Yes	
Record 5	East	BankA	Claus French	Courbet	Gustave	57	60,000	25,000	Yes	Yes
Record 6	East	BankA	Julian Wood	Dupont	Jean	75	31,000	5,000	Yes	Yes
Record 7	West	BankA	Julian Wood	Hugo	Victor	52	58,000	17,000	Yes	
Record 8	West	BankB	Gilbert Sullivan	Cezanne	Paul	40		1,500	Yes	Yes
Record 9	West	BankA	Claus French	Duchamp	Marcel	32	15,000	2,500	Yes	
Record 10	West	BankB	Gilbert Sullivan	Lupin	Arsene	XXX	XXXXX	XXXXX	XXXXXX	XXXXXX
Record 11	West	BankA	Julian Wood							

There are two records with specific features:

1. Record 10 could not be retrieved for security reasons (no access rights).
2. Record 11 was not found, although account manager, Julian Wood, reported it in the CRM.

A simple check of each record against each BER yields the following results:

Records	Customer Name	Customer First Name	Age	Income	Loan Amount	Pay Slip Provided	Default Record Provided	BER 1	BER 2	BER 3	All BERs
Record 1	Dupont	Jean	75	30,000	9,000	No		Y	Y	N	N
Record 2	Proust	Marcel	50	40,000	11,000	Yes	Yes	Y	Y	Y	Y
Record 3	Flaubert	Gustave	35	25,000	11,000	Yes	Yes	Y	Y	Y	Y
Record 4	Monet	Claude		22,000	5,000	Yes		Y	N	Y	N
Record 5	Courbet	Gustave	57	60,000	25,000	Yes	Yes	Y	Y	Y	Y
Record 6	Dupont	Jean	75	31,000	5,000	Yes	Yes	Y	Y	Y	Y
Record 7	Hugo	Victor	52	58,000	17,000	Yes		N	Y	Y	N
Record 8	Cezanne	Paul	40		1,500	Yes	Yes	Y	Y	Y	Y
Record 9	Duchamp	Marcel	32	15,000	2,500	Yes		Y	Y	Y	Y
Record 10	Lupin	Arsene	XXX	XXXXX	XXXXX	XXXXXX	XXXXXX	N	N	N	N
Record 11								N	N	N	N
						Compliant records		8	8	8	6
						# records		11	11	11	11
						DEI		72.73%	72.73%	72.73%	54.55%

The DEI is the ratio of compliant records against the total number of records. Noncompliant records for all three BERs are records #1, #4, #7, #10, and #11. Action in the further steps will be focused on these records (see subsequent sections).

It should be noted that

- Although each BER have a DEI of 72.7%, the global DEI is lower (54.5%), which shows that this model is different from the traditional aggregation models (OLAP).
- Each record counts only for one in the final calculation of DEI (records 10 and 11) although they can be noncompliant to several BERs.

At this stage, we have a level of compliance (DEI) similar to a KPI. However, we have no information regarding the impact in value of noncompliant transactions (records).

21.5.4.3.3 Views

Using the same method, other DEIs can be calculated according to different views: per region, per bank, per account manager, per customer, etc. It is easy to check that the DEI by region yields the following results:

Regions	BER 1	BER 2	BER 3	All
East	100.00%	83.33%	83.33%	66.67%
West	40.00%	60.00%	60.00%	40.00%
All regions	72.73%	72.73%	72.73%	54.55%

Although DEIs by regions (and for other views) are different, the global DEI stays unchanged as the whole set of records is identical and noncompliant records remain the same.

21.5.4.4 Data Excellence Dimensions

Another view called data quality view according to data quality dimensions (called data excellence dimensions (DEDs) in the framework) can be calculated. DEDs are as follows:

- *Uniqueness*: The uniqueness dimension is to allow the identification in a deterministic way of an entity, a relationship, or an event instance within a specific context to execute a specific business process (e.g., the business process must be able to identify the unique address for sending the invoice for a specific customer). In the example, Records #1 and #6 raise an issue regarding the uniqueness dimension.

- *Completeness*: The completeness dimension is to ensure that the data required for a successful execution of a process in a specific domain and context are present in the database (e.g., to pay your supplier, you need its bank account number). In the example, records #4 and #8 are not complete.
- *Accuracy*: The accuracy dimension is to ensure that the data reflect a real-world view within a context and a specific process. In the example, either record #1 or #6 may not be accurate.
- *Non-obsolescence*: The non-obsolescence dimension ensures that the data required to execute a specific process in a specific context are up to date. Either record #1 or #6 may be obsolete.
- *Consistency*: The consistency dimension is to ensure that the data values are delivered consistently across all the databases and systems for the execution of a specific business process in a specific context. In the example, records #1 and #6 may not be consistent.
- *Timeliness*: The timeliness dimension is to enable first-time right delivery of data required to enable flawless execution of business processes and fulfilling the service-level agreements. In the example, record #11 has not been delivered on time.
- *Accessibility*: The accessibility dimension is to ensure that people, systems, or processes have access to data according to their roles and responsibilities. In the example, record #10 is not accessible.

Each DED provides a DEI, and the DEI resulting from all DED is called the GDE index.

21.5.4.5 KVIs

21.5.4.5.1 Definition and Role

A KVI is a measurement of the value and impact of the DEI on the business operations. It consists of

- *Value*: related to the collection of data elements of the DEI that comply with the BERs
- *Impact*: related to the collection of defective data elements of the DEI that do not comply with the BERs

A fundamental KVI represents the key business value and impact affected by a specific BER. A BER could impact multiple KVIs and a specific KVI can be affected by multiple BERs.

The KVI is a fundamental deliverable of the DEF: Through the KVI, the DEF enables multifocal governance linking business management and data management. The business transaction is, therefore, considered as a key component that enables managing data as a company asset. The DEI becomes the pivot that links the BER, the KVI, and the data elements.

21.5.4.5.2 KVI's Guiding Principles

In order to be efficient and effective, the KVI must fill the following requirements:

- *Tangible value*: a KVI must have tangible value to be considered as an asset linked to the data through the DEI.
- *Stewardship*: each KVI must have a clear steward in the business function and at all organizational levels. The steward from the function must practice their accountability striving for the improvement of the said KVI.
- *BERs*: each KVI must be based on defined BERs.
- *Adequate*: the KVI should reflect real and important business factors to enable control or analysis/evaluation of business operations and to enable sharp decision support.
- *Simple and intuitive*: the KVIs should convey their meaning in a compelling way. Their impact on business should be clearly understandable using common sense.
- *Precise and unambiguous*: the measures should provide no room for misinterpretation or result negotiation.
- *Comprehensive*: they should describe all aspects that are relevant to achieving expected results.

- *Manageable:* calculation of indicators and their presentation to interested parties (reporting) must be straightforward and must not involve personnel interaction.
- *Limited in number:* the whole set of measures should be looked at when evaluating performance.

21.5.4.5.3 Example

Back to our loan application management example, the loan business manager of SmartBank can decide to define the KVI as the amount of the loan for each application. The rationale behind it is that the risk for the bank is the amount of money lent to its customers; it is also linked to the risk to lose a transaction if some data are missing for a loan application. More widely, a specific KVI linked to the loss of customer derived to a bad loan application management could be considered.

From the DEI calculation, we have derived that records #1, #4, #7, #10, and #11 are noncompliant: the following table shows the KVI and impact according to the KVI definition for each of the three BERs, all BERs.

The value and impact per BER are calculated by summing, respectively, the loan amount of all compliant records and noncompliant records. For example, for BER1 only, record #7 is noncompliant. The impact is the loan amount of record #7, that is, 17,000€. The KVI (value) is the sum of the loan amount of the compliant records, that is, 70,000€. The total value is 87,000€. If the ratio KVI/total value of 80.9% is slightly better that the DEI (72.7%), the impact can be zeroed by fixing record #7 by providing the information related to the customer default record. The value impact % column in the table is the value impact distribution across noncompliant records. It can be seen that fixing record #7 and record #1 (surgical approach to data quality) would cut the impact by 84%, which may be sufficient for the business.

Records	Customer Name	Customer First Name	Age	Income	Loan Amount	Pay Slip Provided	Default Record Provided	BER 1	BER 2	BER 3	All BERs	Value Impact %
Record 1	Dupont	Jean	75	30,000	9,000	No		Y	Y	N	N	29.03%
Record 2	Proust	Marcel	50	40,000	11,000	Yes	Yes	Y	Y	Y	Y	
Record 3	Flaubert	Gustave	35	25,000	11,000	Yes	Yes	Y	Y	Y	Y	
Record 4	Monet	Claude		22,000	5,000	Yes		Y	N	Y	N	16.13%
Record 5	Courbet	Gustave	57	60,000	25,000	Yes	Yes	Y	Y	Y	Y	
Record 6	Dupont	Jean	75	31,000	5,000	Yes	Yes	Y	Y	Y	Y	
Record 7	Hugo	Victor	52	58,000	17,000	Yes		N	Y	Y	N	54.84%
Record 8	Cezanne	Paul	40		1,500	Yes	Yes	Y	Y	Y	Y	
Record 9	Duchamp	Marcel	32	15,000	2,500	Yes		Y	Y	Y	Y	
Record 10	Lupin	Arsene	XXX	XXXXX	XXXXX	XXXXXX	XXXXXX	N	N	N	N	
Record 11								N	N	N	N	
						Compliant records		8	8	8	6	
						# records		11	11	11	11	
						DEI		72.73%	72.73%	72.73%	54.55%	
						Total value		87,000	87,000	87,000	87,000	
						Impact		17,000	5,000	9,000	31,000	
						KVI		70,000	82,000	78,000	56,000	
						Ratio KVI/Total value		80.46%	94.25%	89.66%	64.37%	

Note that if DEIs for the three different BERs are identical (72.7%), the KVIs are different because each record does not represent the same business value. This is the main reason why the management by KPIs (DEIs) of the industrial age is inadequate as a good KPI may hide a terrible KVI leading to a severe impact for the business. Alternatively, a bad KPI could generate expensive process improvements, which could prove useless with regards to high KVIs.

In the information age, enterprises must shift from a KPI-driven organization to a KVI-driven one. For emphasizing the point, Patrick Kabac has concluded in Givaudan MDM governance initiative that: "*Business understands facts, not theory*" (Kabac, 2010).

21.5.5 Data Excellence Process

Data and information governance mission: *The establishment of accountability and responsibility at all levels to maximize the business value of enterprise data*

Accountability

The willingness and commitment of business executives to be accountable for the definition and management of the BERs of their area and related KVI targets

Responsibility

The willingness and commitment of data managers to be responsible for individual data records assuring the compliance with BER

DG can be operationalized through collaborative governance networks where data stewards can play a pivotal role between business, data management, and IT.

21.5.5.1 Roles

We have defined the key roles at the center of the DEF:

- *Data accountables*: they have BER responsibility. They are part of line of business managers responsible for processes and applications. They define, approve BER and KVI, follow the results, and drive priorities of actions. There is a tree of data accountability called the governance tree. In our example, the loan account manager is data accountable for the loan application process of SmartBank. He or she has responsibility over the local account managers in BankA and BankB in all regions for the loan application process: this defines the governance tree.
- *Data responsibles*: they are the data managers. Part of the local data management, they are responsible for individual source data records for each BER and defect management.

In our example, we suppose that for each bank (BankA and BankB), there is a data responsible per region for customer and loan data. Each data responsible in each bank reports to the bank's global data responsible reporting to the SmartBank's data responsible: this defines the responsibility tree. Note that there could be different data responsibility for customer data and loan application data.

- *Data stewards:* link the business, data management, and IT. They coordinate the setup of the DG structure, DEI, KVIs, and BERs with data accountable. They collaborate with data responsibles and IT.
  In our example, the SmartBank loan account manager has named a data steward dedicated to the loan application management.
- *IT*: part of the data integration team, they support the implementation and development of DEIs and KVIs.

In our example, IT is a central team in the headquarters of SmartBank (Figure 21.14).

21.5.5.2 Description

This chart is a summary of the continuous data excellence process described just before. It demonstrates explicitly how in the DEF, data and information are governed and driven from the business requirements, by the business through data stewards into data management. The data accountable will define the context, BERs and KVIs. By setting target for the KVIs, he or she will give mandate to the data steward to meet it by fixing data issues that impact the value.

21.5.5.3 Example

In our example, the loan account manager has given instruction to the data steward to have a KVI ratio above 94% (i.e., 81,780€). The data steward notes that the current ratio is 64.37%: by fixing records #1 and #7,

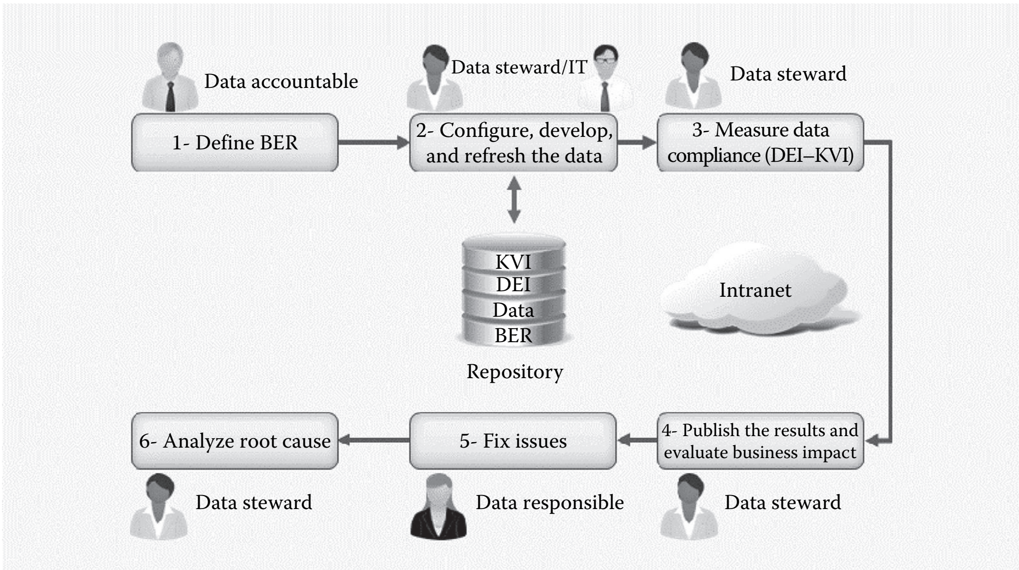

FIGURE 21.14 The continuous data excellence process: Role-based process flow.

he will add 26,000€ to the KVI (56,000€) and reach a 94.25% ratio. Record #1 is managed by the data responsible of BankA in the East, and record #7 is managed by the data responsible of BankA in the West. The data steward will send a requirement to both data managers of BankA to fix those records. Record #1 will be fixed by asking the account manager of BankA in the East region to request the payslip for Jean Dupont and update the loan application system. Record #7 will be fixed by requesting the default record of the customer.

If the root cause analysis shows that there is a defect in a process in BankA, some action might be decided to fix it in order to avoid further defects and value impact.

21.5.5.4 Conclusion

This example shows that the DEF is not a traditional scientific total data quality approach driven by KPIs, but a pragmatic contextual data quality approach driven by value (KVI).

21.5.6 Governance Model

This new approach to cultivate the data assets requires a totally different mind-set as shown in Figure 21.15.

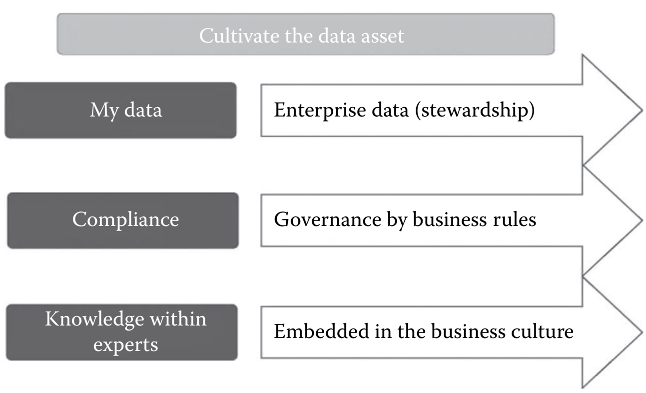

FIGURE 21.15 The governance of the data asset: Change management proposition.

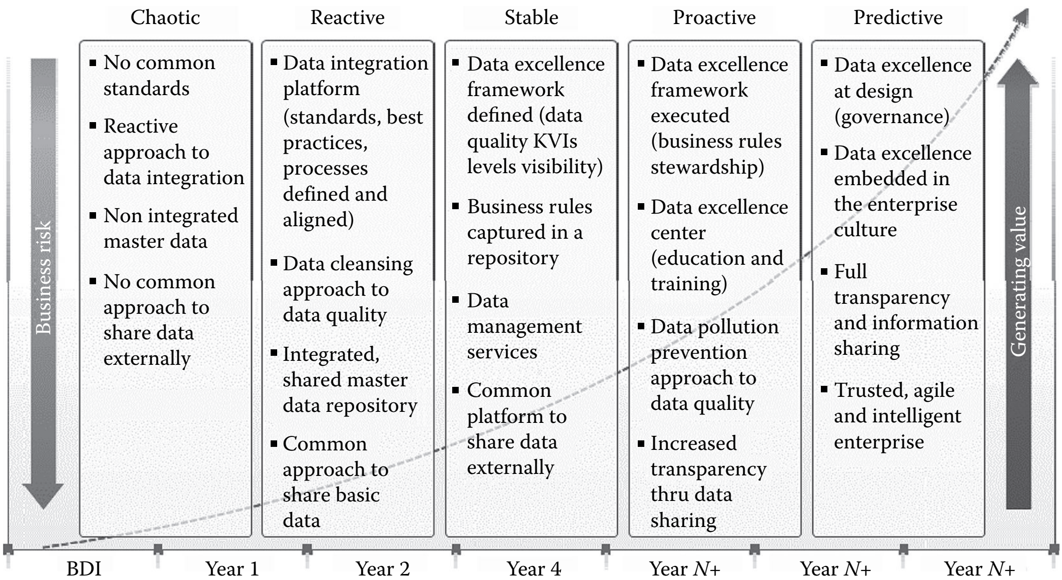

FIGURE 21.16 The data excellence maturity model: From chaos to data excellence.

Shifting from

- Data as a personal power asset to data as an enterprise asset: moving from traditional hierarchal organization to collaborative networks organization
- Compliance data management to a BER- and KVI-driven governance: moving from top-down standardization and MDM approach to "fit for purpose" value-driven DG
- Knowledge within experts to knowledge embedded in the business culture: moving the paradigm from "having the knowledge is the power" to "sharing the knowledge is the power"

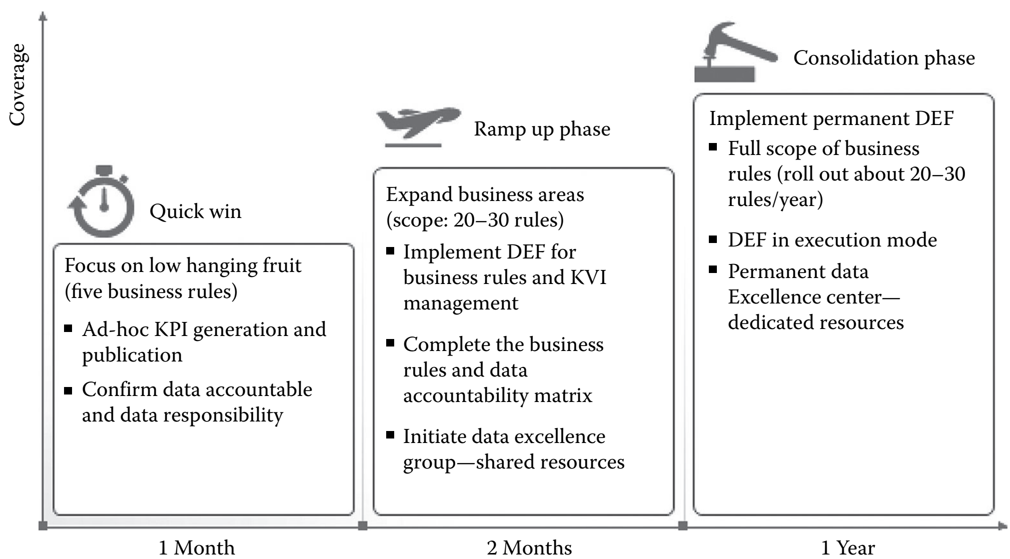

FIGURE 21.17 The DEF: Example of progressive approach.

21.5.7 Maturity Model

Obviously, a KPI-driven organization will not move overnight to the value-driven management. This is a progressive step-by-step evolution illustrated by the data excellence maturity model (Figure 21.16), which tracks organization's progress from the early stages of DG (which is described as "chaotic") to the most mature stages where data are utilized as a core enterprise asset (described as "predictive"; Figure 21.16).

This can be implemented smoothly with short-term returns and small investments for the first phases into a virtuous circle that will lead the enterprise into the data excellence culture (Figure 21.17).

You can achieve DG and high data quality without earthquake in the organization and without costly initiatives. Be progressively incremental with clear communicated business objectives and value of each business rule to be implemented (Figure 21.17). For instance, DG initiative at Nestlé was started with one (1) business rule (El Abed, 2007).

21.6 Conclusion and Future Research on Data Governance

The industrial age was focused on "how" to improve and optimize processes: this approach has proven successful for increasing volumes and lowering costs. However, in the information age characterized by a deluge of data and rules, processing data in a scientific way proves to be time consuming and very costly. In the twenty-first century, business is driven by data and better governance of data means better business. Thus, more organizations start to recognize that they need better data management processes capable of combining business-driven and technical perspectives in order to respond to strategic and operational challenges demanding high-quality corporate data. Both researchers and practitioners consider DG as a promising approach for companies to improve and maintain the quality of corporate data, which is seen as critical for being able to meet strategic business requirements, such as compliance or integrated customer management.

DG specifies the framework that encompasses professionals from both business and IT for decision rights and accountabilities to control and to protect the investments made in data in order to transform them in a real asset for the company. It helps an organization define itself and its strategy and then embed those definitions into core business data ensuring that all of its business processes, systems, projects, and strategies are aligned to create trust and enable consistent executive decision making. DG is to the organization what breathing is to the body. When it is working right, you hardly notice, but when it is not, everything quickly becomes more difficult and labored.

We have been discussing in this chapter the implications of DG for both academics and practitioners and presented the state of the art in the domain. Both sides have proposed a number of DG models and frameworks, which can assist organizations to take off with a DG program. Even though slight differences exist between these models, they all share the basic principle of what a DG program should do: "Defining how to deal with data-related issues."

However, a number of limitations need to be considered. Many models are based on organizational structures that should fit all companies alike. They have, thereby, neglected the fact that each company requires a specific DG configuration that fits a set of contingencies. Furthermore, knowledge has been transferred from IT governance research to DG, and the research on contingencies influencing IT governance models is used as starting point for the contingency research on DG. So far, the proposed contingencies and their impact lack validation in the context of DG. DG model might be characterized by additional parameters, such as a time dimension, which respects the fact that the configuration might evolve over time. In the literature, these issues are investigating and the future direction of DG model is to look toward a contingency approach for DG. Also, one key is to shift the approach from "data-driven" to "value-driven" mind-set meaning that the "business transaction" must be put at the center of DG rather than "data" as advocated by data management trends. This approach for defining and implementing the DG model would help companies to align with shareholders accountability, to assure a sustainable just-in-time data quality enabling the realization of the ultimate "business transaction"

between the shareholders and the customers. The purpose of the "enterprise" is to realize the "business transaction" between the shareholders and the customers and exchange the expected value for each. Therefore, DG must be a mean to enable flawless execution of business strategy maximizing the enterprise potential and revealing the business value of the ultimate transaction.

Design Science Research

Alan R. Hevner
University of South Florida

The proper study of mankind is the science of design.

Herbert Simon

Engineering, medicine, business, architecture and painting are concerned not with the necessary but with the contingent—not with how things are but with how they might be—in short, with design.

Herbert Simon

22.1 Introduction

The design science research (DSR) paradigm has its roots in engineering and the sciences of the artificial (Simon 1996). It is fundamentally a problem-solving paradigm. DSR seeks to enhance human knowledge with the creation of innovative artifacts. These artifacts embody the ideas, practices, technical capabilities, and products through which information and computing technology and systems (ICTS) can be efficiently developed and effectively used. Artifacts are not exempt from natural laws or behavioral theories. To the contrary, their creation relies on existing laws and theories that are applied, tested, modified, and extended through the experience, creativity, intuition, and problem-solving capabilities of the researcher. Thus, the results of DSR include both the newly designed artifact and a fuller understanding of the theories of why the artifact is an improvement to the relevant application context.

Design activities are central to most applied disciplines. Research in design has a long history in many fields including architecture, engineering, education, psychology, and the fine arts (Cross 2001). The ICTS field since its advent in the late 1940s has appropriated many of the ideas, concepts, and methods of design science that have originated in these other disciplines. However, ICTS as composed of

inherently mutable and adaptable hardware, software, and human interfaces provide many unique and challenging design problems that call for new and creative ideas.

The DSR paradigm is highly relevant to ICTS research because it directly addresses two of the key issues of the discipline: the central role of the ICTS artifact (Orlikowski and Iacono 2001) and the importance of professional relevance of ICTS research (Benbasat and Zmud 1999). Design science, as conceptualized by Simon (1996), follows a pragmatic research paradigm that calls for the creation of innovative artifacts to solve real-world problems and to address promising opportunities. DSR in ICTS fields involves the construction of a wide range of *socio-technical* artifacts such as decision support systems (DSSs), modeling tools, governance strategies, methods for software systems development and evaluation, and system change interventions. Thus, DSR in ICTS combines a focus on the ICTS artifact with a high priority on relevance in the application domain.

This chapter begins with a concise introduction to the basic concepts and principles of DSR. The key to appreciating the core ideas and goals of DSR is a clear understanding of how DSR relates to human knowledge. The appropriate and effective consumption and production of knowledge are related issues that researchers should consider throughout the research process—from initial problem selection to the use of sound research methods, to reflection, and to communication of research results in journal, magazine, and conference articles. The chapter concludes with a discussion of ongoing challenges in DSR.

22.2 Design Science Research Concepts and Principles

ICTS artifacts are implemented within an application context (e.g., a business organization) for the purpose of improving the effectiveness and efficiency of that context. The utility of the artifact and the characteristics of the application—its work systems, its people, and its development and implementation methodologies—together determine the extent to which that purpose is achieved. Researchers in the ICTS disciplines produce new ideas to improve the ability of human organizations to adapt and succeed in the presence of changing environments. Such new ideas are then communicated as knowledge to the relevant ICTS communities. In this section, the basic concepts and principles of DSR are surveyed with a focus on its application in ICTS contexts.

22.2.1 Cycle between Design Science Research and Behavioral Science Research

Acquiring ICTS knowledge involves two complementary but distinct paradigms, behavioral science and design science (March and Smith 1995). The behavioral science paradigm has its roots in natural science research methods. It seeks to develop and justify theories (i.e., principles and laws) that explain or predict organizational and human phenomena surrounding the analysis, design, implementation, and use of ICTS. Such theories ultimately inform researchers and practitioners of the interactions among people, technology, and organizations that must be managed if an information system (IS) is to achieve its stated purpose, namely, improving the effectiveness and efficiency of an organization. These theories impact and are impacted by design decisions made with respect to the system development methodology used and the functional capabilities, information contents, and human interfaces implemented within the IS.

Technological advances are the result of innovative, creative DSR processes. If not "capricious," they are at least "arbitrary" (Brooks 1987) with respect to business needs and existing knowledge. Innovations—such as database management systems, high-level languages, personal computers, software components, intelligent agents, object technology, the Internet, and the World Wide Web (WWW)—have had dramatic and at times unintended impacts on the way in which ICTS are conceived, designed, implemented, and managed.

A key insight here is that there is a complementary research cycle between design science and behavioral science to address fundamental problems faced in the productive application of ICTS

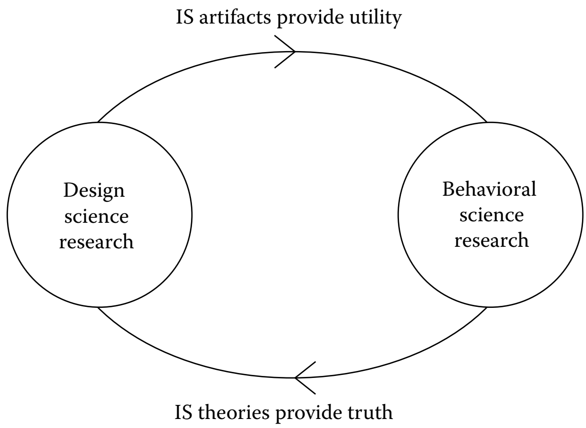

FIGURE 22.1 Complementary nature of design science and behavioral science research.

(see Figure 22.1). Technology and behavior are not dichotomous in an IS. They are inseparable. They are similarly inseparable in ICTS research. These arguments draw from a pragmatist philosophy that argues that truth (justified theory) and utility (artifacts that are effective) are two sides of the same coin and that scientific research should be evaluated in light of its practical implications. In other words, the practical relevance of the research result should be valued equally with the rigor of the research performed to achieve the result.

22.2.2 Design Science Research in ICTS

To achieve a true understanding of and appreciation for the DSR paradigm, an important dichotomy must be faced. Design is both a process (set of activities) and a product (artifact)—a verb and a noun (Walls et al. 1992). It describes the world as acted upon (*processes*) and the world as sensed (*artifacts*). This view of design supports a problem-solving paradigm that continuously shifts perspective between design processes and designed artifacts for the same complex problem. The design process is a sequence of expert activities that produces an innovative product (i.e., the design artifact). The evaluation of the artifact then provides feedback information and a better understanding of the problem in order to improve both the qualities of the product and the design process. This build-and-evaluate loop is typically iterated a number of times before the final design artifact is generated. During this creative process, the design science researcher must be cognizant of evolving both the design process and the design artifact as part of the research.

March and Smith (1995) identify two design processes and four design artifacts produced by DSR in ICTS. The two processes are *build* and *evaluate*. The artifacts are *constructs*, *models*, *methods*, and *instantiations*.

Purposeful artifacts are built to address relevant problems. They are evaluated with respect to the utility provided in solving those problems. Constructs provide the language in which problems and solutions are defined and communicated. Models use constructs to represent a real-world situation—the design problem and its solution space. Models aid problem and solution understanding and frequently represent the connection between problem and solution components enabling exploration of the effects of design decisions and changes in the real world. Methods define processes. They provide guidance on how to solve problems, that is, how to search the solution space. These can range from formal, mathematical algorithms that explicitly define the search process to informal, textual descriptions of "best practice" approaches, or some combination. Instantiations show that constructs, models, or methods can be implemented in a working system. They demonstrate feasibility, enabling concrete assessment

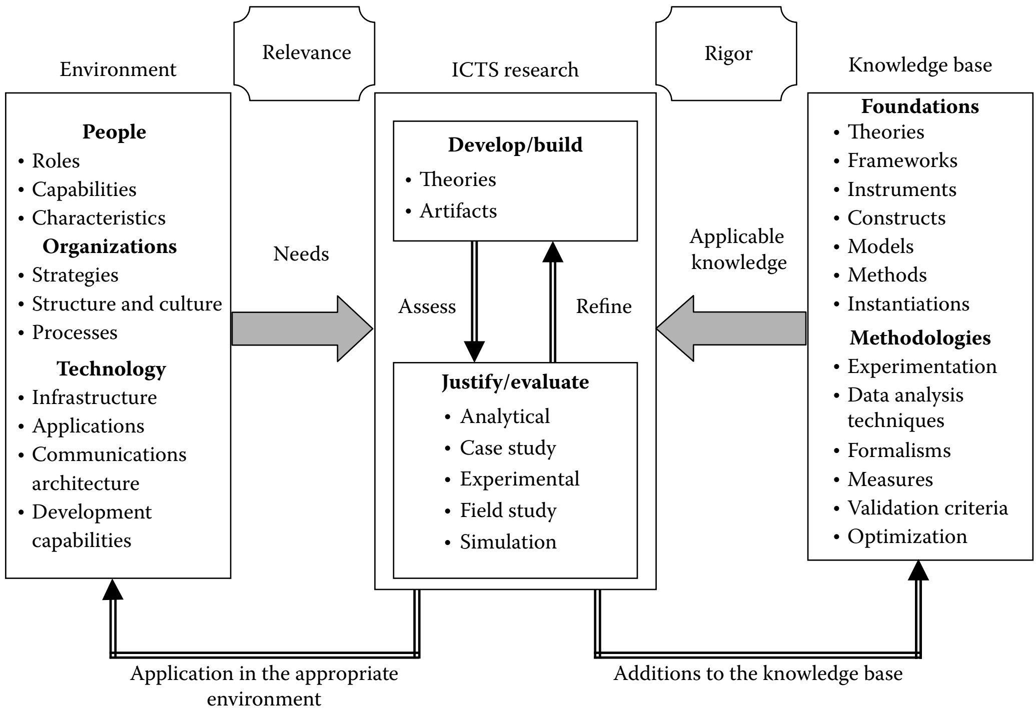

FIGURE 22.2 ICTS research framework. (Adapted from Hevner, A., et al., *MIS Quarterly* 28(1), 75, 2004.)

of an artifact's suitability to its intended purpose. They also enable researchers to learn about the real world, how the artifact affects it, and how users appropriate the design artifact in a real-world context.

Figure 22.2 presents a conceptual framework for understanding, executing, and evaluating research combining behavioral science and design science paradigms (Hevner et al. 2004). The environment defines the problem space in which the phenomena of interest reside. For ICTS research, it is composed of people, organizations, and existing or planned technologies. In it are the goals, tasks, problems, and opportunities that define needs as they are perceived by stakeholders within the organization. Needs are assessed and evaluated within the context of organizational strategies, structure, culture, and existing work processes. They are positioned relative to existing technology infrastructure, applications, communication architectures, and development capabilities. Together these define the "research problem" as perceived by the researcher. Framing research activities to address real stakeholder needs assures research relevance.

Given such articulated needs, IS research is conducted in two complementary phases. Behavioral science addresses research through the *development* and *justification* of theories that explain or predict phenomena related to the identified needs. Design science addresses research through the *building* and *evaluation* of artifacts designed to meet the identified needs. The knowledge base provides the raw materials from and through which ICTS research is accomplished. The knowledge base is composed of foundations and methodologies. Prior research and results from reference disciplines provide foundational theories, frameworks, instruments, constructs, models, methods, and instantiations used in the develop/build phase of a research study. Methodologies provide guidelines used in the justify/evaluate phase. Rigor is achieved by appropriately applying existing foundations and methodologies. In behavioral science, methodologies are typically rooted in data collection and empirical analysis techniques. In design science, computational and mathematical methods are primarily used to evaluate the quality and effectiveness of artifacts; however, empirical techniques may also be employed.

TABLE 22.1 DSR Guidelines

Guideline	Description
Guideline 1: Design as an artifact	Design science research must produce a viable artifact in the form of a construct, a model, a method, or an instantiation
Guideline 2: Problem relevance	The objective of design science research is to develop technology-based solutions to important and relevant business problems
Guideline 3: Design evaluation	The utility, quality, and efficacy of a design artifact must be rigorously demonstrated via well-executed evaluation methods
Guideline 4: Research contributions	Effective design science research must provide clear and verifiable contributions in the areas of the design artifact, design foundations, and/or design methodologies
Guideline 5: Research rigor	Design science research relies upon the application of rigorous methods in both the construction and evaluation of the design artifact
Guideline 6: Design as a search process	The search for an effective artifact requires utilizing available means to reach desired ends while satisfying laws in the problem environment
Guideline 7: Communication of research	Design science research must be presented effectively both to technology-oriented as well as management-oriented audiences

As discussed earlier, DSR is inherently a problem-solving process. The fundamental principle is that knowledge and understanding of a design problem and its solution are acquired in the building and application of an artifact. This principle leads to the statement of seven basic guidelines for the performance of DSR (Hevner et al. 2004). That is, DSR requires the creation of an innovative, purposeful artifact (Guideline 1) for a specified and important problem domain (Guideline 2). Because the artifact is "purposeful," it must yield utility for the specified problem. Hence, thorough evaluation of the artifact is crucial (Guideline 3). Novelty is similarly crucial since the artifact must be "innovative," solving a heretofore unsolved problem or solving a known problem in a more effective or efficient manner (Guideline 4). In this way, DSR is differentiated from the practice of design. The artifact itself must be rigorously defined, formally represented, coherent, and internally consistent (Guideline 5). The process by which it is created, and often the artifact itself, incorporates or enables a search process whereby a problem space is constructed and a mechanism posed or enacted to find an effective solution (Guideline 6). Finally, the results of the DSR project must be communicated effectively (Guideline 7) both to a technical audience (researchers who will extend them and practitioners who will implement them) and to a managerial audience (researchers who will study them in context and practitioners who will decide if they should be implemented within their organizations). Researchers, reviewers, and editors must use their creative skills and judgment to determine when, where, and how to apply each of the guidelines in a specific research project. However, each of these guidelines should be addressed in some manner for DSR to be complete. Table 22.1 summarizes the seven guidelines.

22.2.3 Three DSR Cycles

Key insights can be gained by identifying and understanding the existence of three DSR cycles in any design research project as shown in Figure 22.3 (Hevner 2007). This figure borrows the IS research framework found in (Hevner et al. 2004) and overlays a focus on three inherent research cycles. The *relevance cycle* bridges the contextual environment of the research project with the design science activities. The *rigor cycle* connects the design science activities with the knowledge base of scientific foundations, experience, and expertise that informs the research project. The central *design cycle* iterates between the

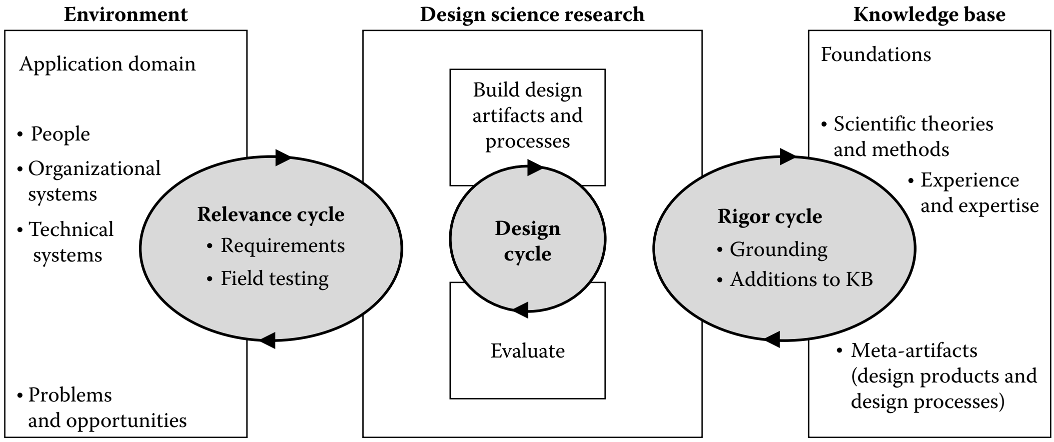

FIGURE 22.3 DSR cycles. (From Hevner, A., *Scand. J. Inform. Syst.*, 19(2), 87, 2007.)

core activities of building and evaluating the design artifacts and processes of the research. These three cycles must be present and clearly identifiable in a DSR project. The following sections briefly expand on the definitions and meanings of each cycle.

22.2.3.1 Relevance Cycle

The relevance cycle initiates DSR within an application context that not only provides the requirements for the research (e.g., the opportunity/problem to be addressed) as inputs but also defines acceptance criteria for the ultimate evaluation of the research results. Does the design artifact improve the environment? How can this improvement be measured? The output from DSR must be returned into the environment for study and evaluation in the application domain. The field study of the artifact can be executed by means of appropriate technology transfer methods such as action research (Sein et al. 2011).

The results of the field testing will determine whether additional iterations of the relevance cycle are needed in this DSR project. The new artifact may have deficiencies in functionality or in its inherent qualities (e.g., performance, usability) that may limit its utility in practice. Another result of field testing may be that the requirements input to the DSR project were incorrect or incomplete with the resulting artifact satisfying the requirements but still inadequate to the opportunity or problem presented. Another iteration of the relevance cycle will commence with feedback from the environment from field testing and a restatement of the research requirements as discovered from actual experience.

22.2.3.2 Rigor Cycle

DSR draws from a vast knowledge base of scientific theories and engineering methods that provides the foundations for rigorous research. Equally important, the knowledge base also contains two types of additional knowledge:

- The experiences and expertise that define the state of the art in the application domain of the research
- The existing artifacts and processes found in the application domain

The rigor cycle provides past knowledge to the research project to ensure its innovation. Consideration of rigor in DSR is based on the researcher's skilled selection and application of the appropriate theories and methods for constructing and evaluating the artifact. DSR is grounded on existing ideas drawn from the domain knowledge base. Inspiration for creative design activity can be drawn from many different sources to include rich opportunities/problems from the application environment, existing artifacts, analogies/metaphors, and theories (Iivari 2007). This list of design inspiration can be expanded to include additional sources of creative insights (Csikszentmihalyi 1996).

Additions to the knowledge base as results of DSR will include any additions or extensions to the original theories and methods made during the research, the new artifacts (design products and processes), and all experiences gained from performing the iterative design cycles and field testing the artifact in the application environment. It is imperative that a DSR project makes a compelling case for its rigorous foundations and contributions lest the research be dismissed as a case of routine design. Definitive research contributions to the knowledge base are essential to selling the research to an academic audience just as useful contributions to the environment are the key selling points to a practitioner audience.

22.2.3.3 Design Cycle

The internal design cycle is the heart of any DSR project. This cycle of research activities iterates rapidly between the construction of an artifact, its evaluation, and subsequent feedback to refine the design further. Simon (1996) describes the nature of this cycle as generating design alternatives and evaluating the alternatives against requirements until a satisfactory design is achieved. As discussed earlier, the requirements are input from the relevance cycle and the design and evaluation theories and methods are drawn from the rigor cycle. However, the design cycle is where the hard work of DSR is done. It is important to understand the dependencies of the design cycle on the other two cycles while appreciating its relative independence during the actual execution of the research.

During the performance of the design cycle, a balance must be maintained between the efforts spent in constructing and evaluating the evolving design artifact. Both activities must be convincingly based in relevance and rigor. Having a strong grounded argument for the construction of the artifact, as discussed earlier, is insufficient if the subsequent evaluation is weak. Artifacts must be rigorously and thoroughly tested in laboratory and experimental situations before releasing the artifact into field testing along the relevance cycle. This calls for multiple iterations of the design cycle in DSR before contributions are output into the relevance cycle and the rigor cycle.

22.2.4 DSR Process Models

The growing interest in performing DSR projects has led to several proposed process models for scheduling and coordinating design activities. Seminal thinking in this area was achieved by Nunamaker and his research group at the University of Arizona (Nunamaker et al. 1990–1991). They claim that the central nature of systems development leads to a multi-methodological approach to ICTS research that consists of four research strategies: theory building, experimentation, observation, and systems development. Systems development corresponds closely to DSR and consists of five stages: conceptual design, constructing the architecture of the system, analyzing the design, prototyping (may include product development), and evaluation. The framework is shown in Figure 22.4.

More recently, Vaishnavi and Kuechler (2008) have extended the general design cycle model of Takeda et al. (1990) to apply specifically to DSR as illustrated in Figure 22.5. In this model, all design begins with awareness of problem. Here, you not only identify the problem but also define it. The next stage is a preliminary suggestion for a problem solution that is drawn from the existing knowledge or theory base for the problem area. Once a tentative design is decided, the next stage is actual development. This is a creative stage where the design is further refined and an actual artifact is produced through many iterations. Once an implementation (or prototype) is ready, it is evaluated according to the functional specification implicit or explicit in the suggestion. Empirical methods are often used in evaluation. There are iterations and feedback involved in these stages cited as circumscription. Finally, a project is terminated and concluded.

Peffers et al. (2008) propose and develop a design science research methodology (DSRM) for the production and presentation of DSR as shown in Figure 22.6. This DSR process includes six steps (problem identification and motivation, definition of the objectives for a solution, design and development, demonstration, evaluation, and communication) and four possible entry points (problem-centered initiation, objective-centered solution, design and development–centered initiation, and client/context initiation). A brief description of each DSR activity follows.

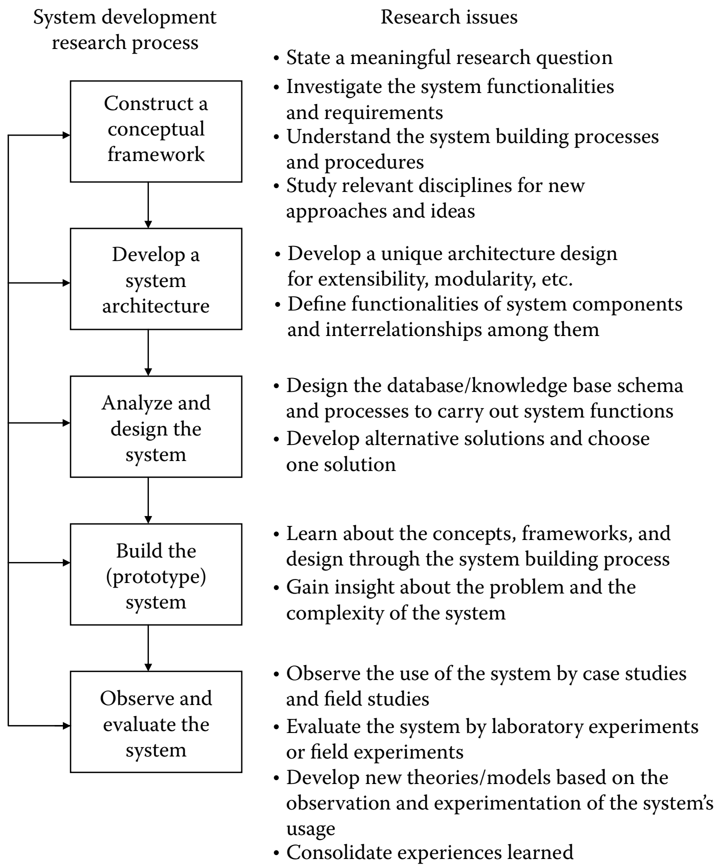

FIGURE 22.4 Systems development research model. (From Nunamaker, J. et al., *J. Manage. Inform. Syst.*, 7(3), 89, 1990–1991.)

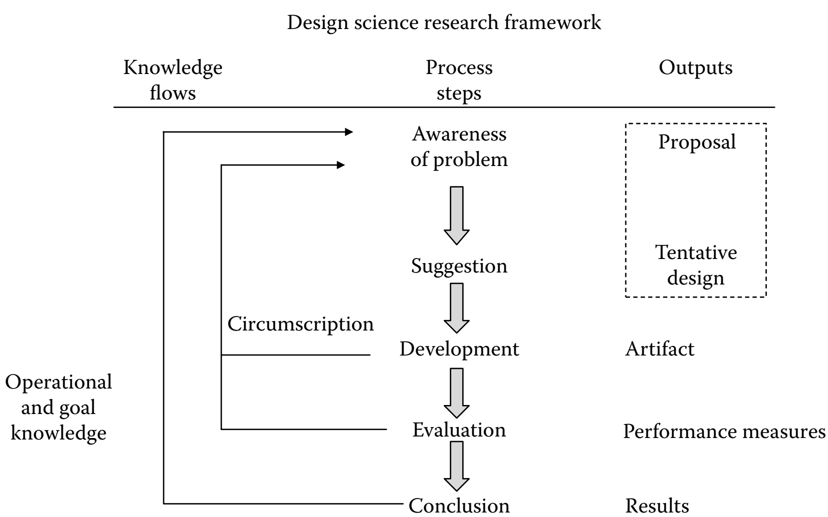

FIGURE 22.5 The general design cycle for DSR. (From Vaishnavi, V. and Kuechler, W., *Design Science Research Methods and Patterns: Innovating Information and Communication Technology*, Auerbach Publications, Boston, MA, 2008.)

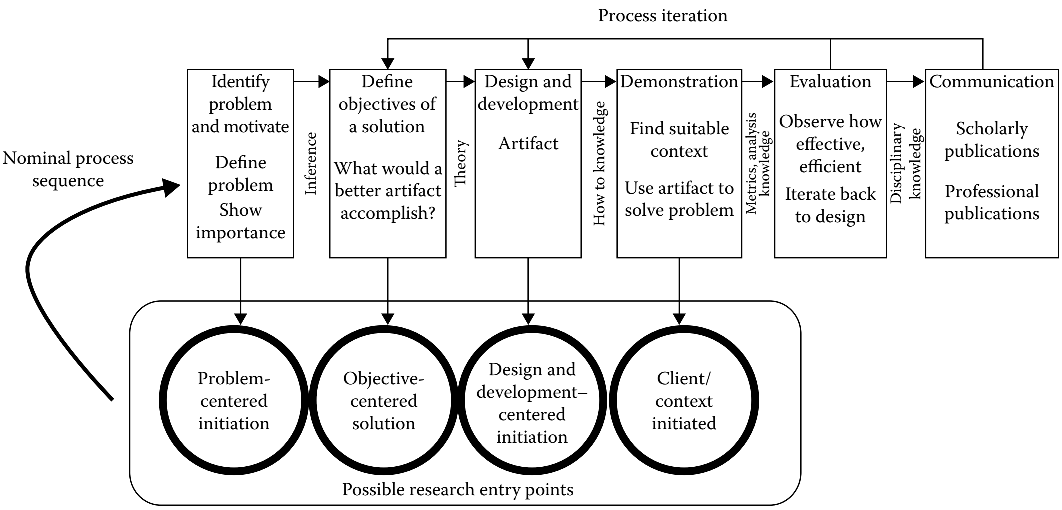

FIGURE 22.6 DSRM process model. (From Peffers, K. et al., *J. MIS*, 24(3), 45, 2008.)

Activity 1: *Problem identification and motivation*. This activity defines the specific research problem and justifies the value of a solution. Justifying the value of a solution accomplishes two things: It motivates the researcher and the audience of the research to pursue the solution and it helps the audience to appreciate the researcher's understanding of the problem. Resources required for this activity include knowledge of the state of the problem and the importance of its solution.

Activity 2: *Define the objectives for a solution*. The objectives of a solution can be inferred from the problem definition and knowledge of what is possible and feasible. The objectives can be quantitative, for example, terms in which a desirable solution would be better than current ones, or qualitative, for example, a description of how a new artifact is expected to support solutions to problems not hitherto addressed. The objectives should be inferred rationally from the problem specification.

Activity 3: Design and development. An artifact is created. Conceptually, a DSR artifact can be any designed object in which a research contribution is embedded in the design. This activity includes determining the artifact's desired functionality and its architecture and then creating the actual artifact.

Activity 4: Demonstration. This activity demonstrates the use of the artifact to solve one or more instances of the problem. This could involve its use in experimentation, simulation, case study, proof, or other appropriate activity.

Activity 5: *Evaluation*. The evaluation measures how well the artifact supports a solution to the problem. This activity involves comparing the objectives of a solution to actual observed results from use of the artifact in context. Depending on the nature of the problem venue and the artifact, evaluation could take many forms. At the end of this activity, the researchers can decide whether to iterate back to step three to try to improve the effectiveness of the artifact or to continue on to communication and leave further improvement to subsequent projects.

Activity 6: Communication. Here, all aspects of the problem and the designed artifact are communicated to the relevant stakeholders. Appropriate forms of communication are employed depending upon the research goals and the audience, such as practicing professionals.

22.2.5 Design Theory

In the natural and social sciences, well-developed or mature theory refers to a cohesive body of knowledge (BOK) that has certain distinguishing characteristics. "Scientific" knowledge, as opposed to common-sense knowledge, has (1) explanations of why statements and beliefs hold, (2) delimitation of the boundaries within which beliefs hold, (3) a logically consistent set of statements and beliefs,

(4) precision in the language used to specify constructs and statements, (5) abstraction in the formulation of generalized concepts and statements, and (6) persistent testing of arguments and beliefs against available evidence (Nagel 1979, pp. 2–14). Gregor (2006) provides a comprehensive look at various theories proposed in ICTS disciplines and explores the structural nature and ontological character of these theories. She summarizes and shows theories as abstract entities that aim to *describe*, *explain*, and *enhance understanding* of the world. In some cases, theory provides *predictions* of what will happen in the future and gives bases for intervention and action. The type of theory that formalizes knowledge in DSR is termed design theory in Gregor's (2006) taxonomy. This type of theory gives prescriptions for design and action: It says how to do something. As with other forms of theory, design theory must have some degree of generality.

Walls et al. (1992), early proponents of design theory in IS, stress that a design theory must include components that are at a meta-level. A design theory "does not address a single problem but rather a class of problems" (p. 42). They formally specify the seven components of design theory in ICTS as follows:

1. *Meta-requirements*: The class of goals to which the theory applies
2. *Meta-design*: The class of artifacts hypothesized to meet the meta-requirements
3. *Kernel* design product theories*: Theories from natural and social sciences that govern design requirements
4. *Testable design product hypotheses*: Statements required to test whether the meta-design satisfies meta-requirements
5. *Design method*: A description of the procedures for constructing the artifact
6. *Kernel design process theories*: Theories from natural or social sciences that inform the design process
7. *Testable design process hypotheses*: Statements required to test whether the design method leads to an artifact that is consistent with meta-design

Extending this stream of thought, Gregor and Jones (2007) propose that a DSR project should produce a design theory or provide steps toward a design theory. Their view, as expressed similarly in other branches of science, is that all research should result in a contribution to knowledge in the form of partial theory, incomplete theory, or even some particularly interesting and perhaps surprising empirical generalization in the form of a new design artifact (Merton 1968; Sutton and Staw 1995).

Gregor and Jones (2007) provide arguments to show that well-developed design knowledge can satisfy these criteria for scientific knowledge and also the criteria for theory that Dubin (1978) specifies. They argue that any DSR design theory should include as minimum criteria the following core components:

1. *Purpose and scope*: "What the system is for," the set of meta-requirements or goals that specifies the type of artifact to which the theory applies and in conjunction also defines the scope, or boundaries, of the theory
2. *Constructs*: Representations of the entities of interest in the theory
3. *Principles of form and function*: The abstract "blueprint" or architecture that describes an IS artifact, either product or method/intervention
4. *Artifact mutability*: The changes in state of the artifact anticipated in the theory, that is, what degree of artifact change is encompassed by theory
5. *Testable propositions*: Truth statements about the design theory
6. *Justificatory knowledge*: The underlying knowledge or theory from the natural or social or design sciences that gives a basis and explanation for the design (kernel theories)

* The term "kernel theories" is used by Walls et al. (1992) to denote descriptive theories from natural and social sciences that are used to support and explain design theories. In general, kernel theory refers to the descriptive theory that provides the underpinning justificatory knowledge that informs artifact construction and explains why artifacts work (Gregor and Jones 2007).

Additional design theory components may be

8. *Principles of implementation*: A description of processes for implementing the theory (either product or method) in specific contexts
9. *Expository instantiation*: A physical implementation of the artifact that can assist in representing the theory both as an expository device and for purposes of testing

The decision whether to present DSR results as design theory will depend on the levels of artifact abstraction (see Section 22.3.3) and desired generality in the research. An artifact that is presented with a higher degree of abstraction can be generalized to other situations and is more interesting than a simple descriptive case study of what happened in one situation. What distinguishes design theory, however, is that it includes kernel theory to explain why the artifact works and testable propositions. If research can be expressed in these terms, with more explanation, more precision, more abstraction, and more testing of beliefs facilitated, then there is a move toward a more mature and well-developed BOK (Nagel 1979). However, it is important for researchers to clearly understand what contributions can be claimed in a DSR project. Researchers should not force results into a design theory description if such a presentation is not appropriate or useful. Often, DSR results can be presented effectively as artifact representations and rigorous evaluations of the artifact in use. Only if expression of these results in a design theory provides a useful generalization for extending knowledge in the problem or solution domains should such a design theory be presented.

22.3 Knowledge Contributions of Design Science Research

Contributing to human knowledge is seen as the key criterion for the credibility and publication of DSR. The appropriate and effective consumption and production of knowledge are fundamental issues that researchers should consider throughout the research process—from initial problem selection to the use of sound research methods, to reflection, and to communication of research results in journal and conference articles. Experience shows that many authors, reviewers, and editors struggle to present DSR work well with a clear demonstration of how their research contributes to knowledge. The difficulties here likely arise from a combination of factors, which include the relative youth of the ICTS disciplines and the comparatively recent recognition of DSR as a distinct, yet legitimate, research paradigm. The potential impact of rigorous DSR is lost or marginalized when knowledge contributions are inadequately positioned and presented.

22.3.1 Types of Knowledge

Drawing from the economics of knowledge field, useful DSR knowledge can be divided into two distinct types (see Mokyr 2002). *Descriptive knowledge* (denoted Ω or omega) is the "what" knowledge about natural phenomena and the laws and regularities among phenomena. *Prescriptive knowledge* (denoted Λ or lambda) is the "how" knowledge of human-built artifacts. Figure 22.7 shows that both Ω knowledge and Λ knowledge comprise a knowledge base for a particular DSR application context.

22.3.1.1 Descriptive Knowledge

Descriptive knowledge has two primary forms. The descriptions of natural, artificial, and human-related phenomena are composed of observations, classifications, measurements, and the cataloging of these descriptions into accessible forms. Additionally, we discover knowledge of the sense-making relationships among the phenomena. This sense-making is represented by natural laws, principles, regularities, patterns, and theories. Together, phenomena and their sense-making relationships provide the natural, artificial, and human (social) science bases for the world in which we live. An addition of knowledge to Ω is a *discovery* of new facts or laws that have always existed but have not been understood and described until now. Over time, the Ω knowledge base accumulates the "BOK" surrounding a natural, artificial, social, or human phenomenon. Such knowledge resides in people's minds or in external storage devices (e.g., data repositories).

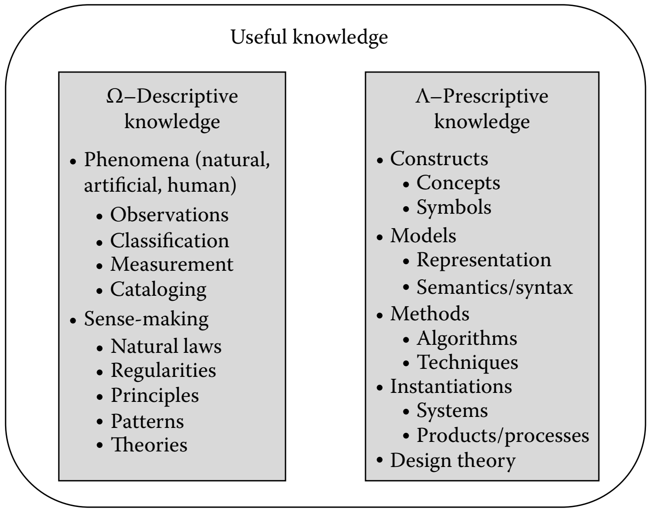

FIGURE 22.7 The DSR knowledge base. (From Gregor, S. and Hevner, A., *Management Information Systems Quarterly*, 2013.)

22.3.1.2 Prescriptive Knowledge

Prescriptive knowledge concerns artifacts designed by humans to improve the natural world. Simon (1996) labels such knowledge as belonging to the sciences of the artificial. March and Smith (1995) define four types of prescriptive knowledge: constructs, models, methods, and instantiations. Design theories are also forms of presenting prescriptive knowledge, so the Λ knowledge base includes the following:

- *Constructs*, which provide the vocabulary and symbols used to define and understand problems and solutions; for example, the constructs of "entities" and "relationships" in the field of information modeling. The correct constructs have a significant impact on the way in which tasks and problems are conceived, and they enable the construction of models for the problem and solution domains.
- *Models*, which are designed representations of the problem and possible solutions. For example, mathematical models, diagrammatical models, and logic models are widely used in the ICTS field. New and more useful models are continually being developed. Models correspond to "principles of form" in the Gregor and Jones (2007) taxonomy: the abstract blueprint of an artifact's architecture, which show an artifact's components and how they interact.
- *Methods*, which are algorithms, practices, and recipes for performing a task. Methods provide the instructions for performing goal-driven activities. They are also known as techniques (Mokyr 2002) and correspond to "principles of function" in the Gregor and Jones (2007) taxonomy and Bunge's (1998) technological rules.
- *Instantiations*, which are the physical systems that act on the natural world, such as an IS that stores, retrieves, and analyzes customer relationship data. Instantiations can embody design knowledge, possibly in the absence of more explicit description. The structural form and functions embodied in an artifact can be inferred to some degree by observing the artifact.
- *A design theory*, which is an abstract, coherent body of prescriptive knowledge that describes the principles of form and function, methods, and justificatory theory that are used to develop an artifact or accomplish some end (Gregor and Jones 2007).

Adding knowledge to Λ concerns *inventions*, that is, things that would not exist except for human creativity.

22.3.2 Roles of Knowledge in DSR

Figure 22.8 illustrates the various relationships and interactions of Ω knowledge and Λ knowledge in the performance of DSR. DSR begins with an important opportunity, challenging problem, or insightful vision/conjecture for something innovative in the application environment (Hevner et al. 2004; Hevner 2007; Iivari 2007). Research questions typically center on how to increase some measure of operational utility via new or improved design artifacts. To study the research questions, the first enquiry is: What do we know already? From what existing knowledge can we draw? Both Ω and Λ knowledge bases are investigated for their contributions to the grounding of the research project. Such investigations are contingent on researchers having ready and efficient access to both knowledge bases.

From the Ω base, the researcher appropriately draws relevant descriptive and propositional knowledge that informs the research questions. Relevant knowledge may be drawn from many different elements in Ω. This would include existing justificatory (i.e., kernel) theories that relate to the goals of the research. At the same time, from the Λ base, the researcher investigates known artifacts and design theories that have been used to solve the same or similar research problems in the past. The objective is to provide a baseline of knowledge on which to evaluate the novelty of new artifacts and knowledge resulting from the research. In many cases, the new design research contribution is an important extension of an existing artifact or the application of an existing artifact in a new application domain. The success of a DSR project is predicated on the research skills of the team in appropriately drawing knowledge from both Ω and Λ bases to ground and position the research; the teams' cognitive skills (e.g., creativity, reasoning) in designing innovative solutions; and the teams' social skills in bringing together all the individual members' collective and diverse intelligence via effective teamwork.

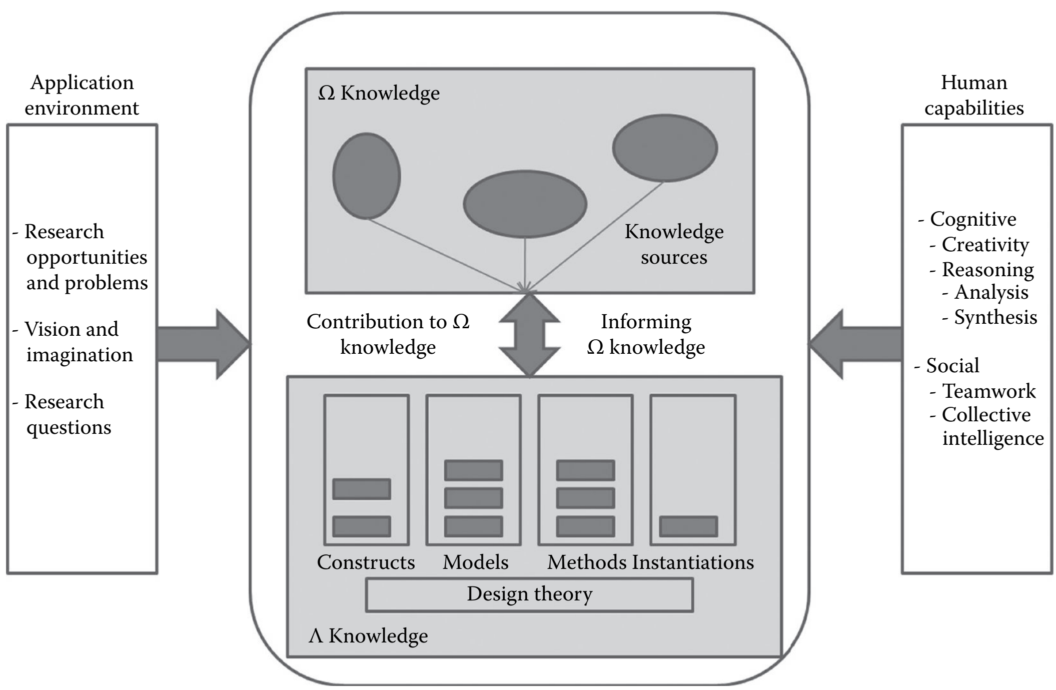

FIGURE 22.8 The roles of knowledge in DSR. (From Gregor, S. and Hevner, A., *Management Information Systems Quarterly*, 2013.)

DSR activities include the building of innovative artifacts, evaluating the utility of the artifacts, and reflecting on what has been learned in the research process. The researcher adds new knowledge to the Λ base with the design of new constructs, models, methods, and instantiations and with the development of new design theories or the more complete development of nascent design theories. The results of the evaluations then may also be a contribution to Ω knowledge in the form of propositions such as "System A outperforms System B in Environment C by Measurement D." Thus, we assert that rigorous DSR produces both Λ and Ω knowledge as research contributions.

22.3.3 ICTS Artifact

Information technology (IT) artifact plays a key role in knowledge contribution. In general, the term artifact refers to a thing that has, or can be transformed into, a material existence as an artificially made object (e.g., model, instantiation) or process (e.g., method, software). Many IT artifacts have some degree of abstraction but can be readily converted to a material existence; for example, an algorithm converted to operational software. In contrast, a theory is more abstract, has a nonmaterial existence, and contains knowledge additional to the description of a materially existing artifact. The construction of an artifact and its description in terms of DSR concepts and principles can be seen as steps in the process of developing more comprehensive bodies of knowledge or design theories.

Table 22.2 shows three maturity levels of DSR artifact types with examples of each level (Purao 2002; Gregor and Hevner 2013). A specific DSR research project can produce artifacts on one or more of these levels ranging from specific instantiations at Level 1 in the form of products and processes to more general (i.e., abstract) contributions at Level 2 in the form of nascent design theory (e.g., constructs, design principles, models, methods, technological rules), to well-developed design theories about the phenomena under study at Level 3. Note that "artifact or situated implementation" (Level 1) is considered a knowledge contribution, even in the absence of abstraction or theorizing about its design principles or architecture because the artifact can be a research contribution in and of itself. Demonstration of a novel artifact can be a research contribution that embodies design ideas and theories yet to be articulated, formalized, and fully understood.

22.3.4 A DSR Knowledge Contribution Framework

Gregor and Hevner (2013) posit a DSR knowledge contribution framework as an effective way to understand and position a DSR project's research contributions. Clearly identifying a knowledge contribution

TABLE 22.2 DSR Artifact Contribution Types

	Contribution Types	Example Artifacts
More abstract, complete, and mature knowledge	Level 3: Well-developed design theory about embedded phenomena	Design theories (mid-range and grand theories)
↕ ↕ ↕ ↕	Level 2: Nascent design theory—knowledge as operational principles/architecture	Constructs, methods, models, design principles, and technological rules.
More specific, limited, and less mature knowledge	Level 1: Situated implementation of artifact	Instantiations (software products or implemented processes)

Source: Gregor, S. and Hevner, A., *Management Information Systems Quarterly*, 2013.

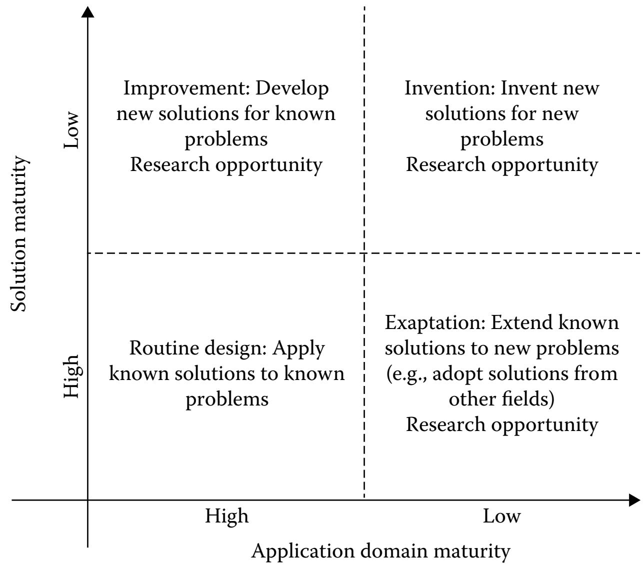

FIGURE 22.9 DSR knowledge contribution framework. (From Gregor, S. and Hevner, A., *Management Information Systems Quarterly*, 2013.)

is often difficult in DSR because it depends on the nature of the designed artifact (as seen in Table 22.2), the state of the field of knowledge, the audience to whom it is to be communicated, and the publication outlet. In addition, the degree of knowledge contribution can vary: there might be incremental artifact construction or only partial theory building, but this may still be a significant and publishable contribution. The size of the knowledge increase could be offset by the practical impact in a knowledge area.

A fundamental issue is that nothing is really "new." Everything is made out of something else or builds on some previous idea. When is something really novel or a significant advance on prior work? This problem is highly relevant when considering patents and intellectual property. A DSR project has the potential to make different types and levels of research contributions depending on its starting points in terms of *problem maturity* and *solution maturity*. Figure 22.9 presents a 2×2 matrix of research project contexts and potential DSR research contributions. The x-axis shows the maturity of the problem context from high to low. The y-axis represents the current maturity of artifacts that exist as potential starting points for solutions to the research question, also from high to low.

For each quadrant, research contributions are made in terms of different levels of artifact/theory in DSR and also in terms of contributions to and flows between Ω and Λ knowledge bases.

22.3.4.1 Invention: New Solutions for New Problems

True invention is a radical breakthrough—a clear departure from the accepted ways of thinking and doing. The invention process can be described as an exploratory search over a complex problem space that requires the cognitive skills of curiosity, imagination, creativity, insight, and knowledge of multiple realms of inquiry to find a feasible solution. While this process of invention is perhaps ill-defined, invention activities can still be considered DSR when the result is an artifact that can be applied and evaluated in a real-world context and when new knowledge is contributed to the Ω and/or Λ knowledge bases.

DSR projects in this quadrant will entail research in new and interesting applications where little current understanding of the problem context exists and where no effective artifacts are available as solutions. In fact, so little may be known about the problem that research questions may not even have been raised before. Research contributions in this quadrant result in recognizably novel artifacts or inventions. In this category, the idea of the artifact itself is new, for example, the first bicycle or the first DSS. Here, a recognized problem may not necessarily exist and the value of a solution may be unclear.

As Simon (1996) says, the researcher may be guided by nothing more than "interestingness." In part, a key contribution is the conceptualization of the problem itself. Knowledge flows in the invention quadrant are typically from prescriptive to descriptive. The new artifact is invented and then other researchers see it employed in use and begin to formulate descriptive knowledge about its use in context (in a different quadrant).

A well-known exemplar of invention in the IT field is found in Agrawal et al. (1993). This research developed the first full conceptualization of mining databases for association rules as well as an efficient method for discovering them. As an "invention," this paper has generated and influenced whole new fields of research broadly described as data analytics and business intelligence (Davenport and Harris 2007). Other examples of IT inventions would include the first thinking on DSSs by Scott-Morton (1967) and the subsequent evolution of DSS into executive IS and group DSSs (Nunamaker et al. 1991).

22.3.4.2 Improvement: New Solutions for Known Problems

The goal of DSR in the improvement quadrant is to create better solutions in the form of more efficient and effective products, processes, services, technologies, or ideas. Researchers must contend with a known application context for which useful solution artifacts either do not exist or are clearly suboptimal. Researchers will draw from a deep understanding of the problem environment to build innovative artifacts as solutions to important problems. The key challenge in this quadrant is to clearly demonstrate that the improved solution genuinely advances on previous knowledge. Several examples of improvement DSR projects are listed below.

- Better data mining algorithms for knowledge discovery (extending the initial ideas invented by Agrawal et al. (1993)), for example, (Fayyad et al. 1996; Zhang et al. 2004; Witten et al. 2011).
- Improved recommendation systems for use in e-commerce, for example, (Herlocker et al. 2004; Adomavicius and Tuzhilin 2005).
- Better technologies and use strategies for saving energy in IT applications, for example, (Donnellan et al. 2011; Watson and Boudreau 2011).
- Improved routing algorithms for business supply chains, for example, (van der Aalst and Hee 2004; Liu et al. 2005).

Improvement DSR is judged first on its ability to clearly represent and communicate the new artifact design. The presentation will show how and why the new solution differs from current solutions. The reasons for making the improvement should be formally grounded in kernel theories from the Ω knowledge base. Once the design improvement is described, then the artifact must be evaluated to provide convincing evidence of its improvement over current solutions. Improvement may be in the form of positive changes in efficiency, productivity, quality, competitiveness, market share, and other quality measures, depending on the goals of the research.

In the improvement quadrant, DSR projects make contributions to the Λ knowledge base in the form of artifacts at one or more levels as described in Table 22.2. Situated instantiations (Level 1) are often constructed to evaluate the level of improvements in comparison with instantiations of the existing solution artifacts. As appropriate, more general artifacts (Level 2) in the form of constructs, methods, models, and design principles are proposed as research improvements. In addition, new Λ knowledge may be formulated as midrange design theory (Level 3) as a result of improved understanding of the problem and solution spaces. Furthermore, the evaluations of the improved artifact may lead to knowledge contributions to the Ω knowledge base in the form of expanded understanding of the kernel theories or the development of new behavioral theories of the artifact in use.

22.3.4.3 Exaptation: Known Solutions Extended to New Problems

Original ideas often occur to individuals who have training in multiple disciplines of thought. Such training allows interconnections and insights among the fields to result in the expropriation of artifacts in one field to solve problems in another field. Thus, there may exist a research situation in which

existing artifacts are available but are suboptimal. However, effective artifacts may exist in related problem areas that may be adapted or, more accurately, exapted* to the new problem context. In this quadrant are contributions where design knowledge that already exists in one field is extended or refined so that it is extendable to some new application area. In exaptation, one needs to justify that the extension of known design knowledge into a new field is nontrivial and interesting.

This type of research is common in ICTS fields, where new technology advances inspire new applications and a consequent need to test or refine prior ideas. Often, these new advances open opportunities for the exaptation of theories and artifacts to new fields. Several classic exemplars of exaptation in ICTS research are as follows:

- Codd's exaptation of relational mathematics to the problem of database systems design, which led to relational database concepts, models, methods, and instantiations (Codd 1970, 1982).
- Berners-Lee's (2000) original concept of the WWW was one of simply sharing research documents in a hypertext form among multiple computers. Soon, however, many individuals saw the potential of this rapidly expanding interconnection environment to exapt applications from old platforms to the WWW platforms. These new Internet applications were very different from previous versions and added many new artifacts to Λ knowledge.
- Berndt et al. (2003) research on the CATCH data warehouse for health-care information. Well-known methods of data warehouse development (e.g., Inmon 1992) were exapted to new and interesting areas of health-care systems and decision-making applications.

In the exaptation quadrant, similar to the improvement quadrant, DSR can make contributions to the Λ knowledge base in the form of artifacts at all three levels, as appropriate, to the research project goals. Ω-knowledge contributions may also be produced via a greater understanding of the new artifacts in use.

22.3.4.4 Routine Design: Known Solutions for Known Problems

Routine design occurs when existing knowledge for the problem area is well understood and when existing artifacts are used to address the opportunity or question. Research opportunities are less obvious, and these situations rarely require DSR to solve the given problem. In this quadrant is work that would not normally be thought of as contributing to research because existing knowledge is applied in familiar problem areas in a routine way. However, routine work may in some cases lead to surprises and discoveries, but, in such cases, these discoveries will likely involve moving the research to one of the other quadrants.

It is important that high-quality professional design or system building be clearly distinguished from DSR. Professional design is the application of existing knowledge to organizational problems, such as constructing a financial or marketing IS using "best practice" artifacts (constructs, models, methods, and instantiations) that exist in the knowledge base. The key differentiator between professional design and DSR is the clear identification of contributions to the Ω and Λ knowledge bases and the communication of the contribution to the stakeholder communities.

In the early stages of a discipline, or with significant changes in the environment, each new artifact created for that discipline or changed environment is "an experiment" that "poses a question to nature" (Newell and Simon 1976, p. 114). Existing knowledge is used where appropriate; however, often the requisite knowledge is nonexistent. In other words, the knowledge base is inadequate. Reliance on creativity and trial-and-error searches are characteristic of such research efforts. Because DSR results are codified in the knowledge base, they have the potential to become "best practices." Professional design and system building then become the routine application of the knowledge base to known problems.

* In biological evolution, *exaptation* is the adaptation of a trait for a different purpose than its original purpose. The classic example, featured in Gould and Vrba (1982), is the exaptation of bird feathers to the purposes of flight from the original purposes of temperature regulation.

22.4 Summary and Design Science Research Challenges

DSR is a widely practiced form of enquiry due to the natural desire of researchers to improve things. For some it is not enough to study and understand why nature is as it is, but they want to know how to improve the way it is. DSR attempts to focus creativity into the design and construction of artifacts that have proven utility in application contexts.

Design as a research paradigm focuses on the construction and evaluation of novel artifacts that enable the solution of important problems for which extant theory (descriptive knowledge) and current designs (prescriptive knowledge) are inadequate. It utilizes theory and design knowledge but is fundamentally a creative activity in which new knowledge is acquired through the building and use of novel problem-solving artifacts. That knowledge must be tested through the evaluation of the produced artifact. Rigorous testing results in a demonstration that the design can be utilized to solve real problems.

Designs have no special dispensation from the laws of nature. Hence, natural science research methods are utilized in a natural research cycle (Figure 22.1) to gain an understanding of why a design works and to specify contingencies upon it. The resultant theories provide principles that can then become part of the "best practice" and new research opportunities kick off a new cycle of DSR.

As the ICTS fields move forward to achieve a fuller appreciation and use of DSR, there exist a number of exciting challenges to be faced. To conclude this chapter, a few of these challenges are summarized.

22.4.1 DSR and Wicked Problems

DSR in ICTS addresses what are considered to be *wicked problems* (Rittel and Webber 1984; Brooks 1987), that is, those problems characterized by

- Unstable requirements and constraints based on ill-defined environmental contexts
- Complex interactions among subcomponents of the problem
- Inherent flexibility to change design processes as well as design artifacts (i.e., malleable processes and artifacts)
- A critical dependence upon human cognitive abilities (e.g., creativity) to produce effective solutions
- A critical dependence upon human social abilities (e.g., teamwork) to produce effective solutions

Thus, the execution of effective DSR calls upon refined cognitive and social skills in the research team. DSR requires environments that support and enhance such human skills.

22.4.2 Design as Research versus Researching Design

DSR has been interpreted as including two distinctly different classes of research—"design as research" and "researching design." While this chapter focuses on the former class of research, it is important to recognize the existence and importance of both types of research.

Design as research encompasses the idea that doing innovative design that results in clear contributions to the knowledge base constitutes research. Knowledge generated via design can take several forms including constructs, models, methods, instantiations, and design theory. DSR projects are often performed in a specific application context, and the resulting designs and research contributions may be clearly influenced by the opportunities and constraints of the given application domain. Additional research may be needed to generalize the research results to broader domains. Design as research, thus, provides an important strand of research that values research outcomes that focus on improvement of an artifact in a specific domain as the primary research concern and, then, seeks a broader, more general, understanding of theories and phenomena surrounding the artifact as an extended outcome.

Researching design shifts the focus to a study of designs, designers, and design processes. The community of researchers engaged in this mode of research was organized under the umbrella of the Design

Research Society starting as early as the mid-1960s. Because of their focus on methods of designing, they have been able to articulate and follow the goal of generating domain-independent understanding of design processes. Their investigations have been focused largely in the fields of architecture, engineering, and product design. Although it is difficult to provide unambiguous and universally accepted definitions of design processes, working definitions suggest designing is an iterative process of planning, generating alternatives, and selecting a satisfactory design. Examples of work from this stream, therefore, include use of representations and languages (Oxman 1997), use of cognitive schemas (Goldschmidt 1994), and theoretical explorations (Love 2002).

Although similarities are many, the two fields of design study have been different in their focus and trajectory. Of the differences, three are most visible. First, design as research emphasizes the domain in which the design activity will take place, placing a premium on innovativeness within a specific context. In contrast, researching design emphasizes increased understanding of design methods often independent of the domain. Second, the domains of study for the first subfield have typically been the ICTS disciplines as opposed to architecture and engineering for the second. Finally, the closest alliances from the design as research have been formed with disciplines such as computer science, software engineering, and organization science. Researching design is more closely allied with cognitive science and professional fields such as architecture and engineering.

22.4.3 Innovation and DSR

An emerging focus on design thinking has driven transformations in organizations to achieve competitive advantages in the marketplace via the introduction of new products and services (Brown 2009; Martin 2009; Verganti 2009). The need for continual innovation to support future growth and sustainability has led to organizations devoting significant attention and resources to innovation activities.

An intriguing question is how the research fields of DSR and innovation are related. Both disciplines continue to evolve rapidly, with research agendas driven by researchers with deep expertise in either of the two fields. However, little attention has been given to identifying how the concepts of DSR and innovation impinge on each other. A recent investigation based on a case study of the innovation process implemented in Chevron suggests that there are key insights that can be drawn from the DSR guidelines that can potentially impact and improve organizational innovation processes (Anderson et al. 2011). A future objective is to also explore the impacts going in both directions: How can successful innovation processes inform and improve DSR activities? How can successful DSR processes inform and improve innovation activities?

22.4.4 Presentation of DSR Contributions

The DSR community lags the behavioral science community in having useful templates for communicating knowledge contributions. Helpful advice for preparing behavioral research for publication is provided by numerous authors including Bem (2003) for psychology, Perry (1998) for marketing, and Neumann (2006) for the social sciences in general.

Some basic guidance on presenting DSR knowledge contributions is given in work including Hevner et al. (2004), Hevner and Chatterjee (2010), Peffers et al. (2008), Vaishnavi and Kuechler (2008), Zobel (2005), and Sein et al. (2011). This guidance is not, however, highly detailed. In addition, the treatment of publication schema for DSR is scant. In part, this problem arises because much of the work on DSR sees the development of the artifact itself as the whole point and, accordingly, there has been little emphasis on what it means to make a contribution to generalized knowledge. Gregor and Hevner (2013) address this gap in a recent paper on the positioning and presenting of DSR with a focus on knowledge contributions.

A particular issue is adequately describing a design artifact in a scientific journal. Describing the complexities of an artifact within the confines of a journal article is not easy. The level of design detail

in a journal paper will vary based on the application domain, the designed artifact, and the audience to which the presentation is made. The increased use of on line appendices, data repositories, and executable systems to supplement DSR presentations in journals will become more pervasive for these presentation challenges.

22.4.5 DSR Is Perishable

Rapid advances in ICTS technology can invalidate DSR results before they are implemented effectively in the business environment or, just as importantly to managers, before adequate payback can be achieved by committing organizational resources to implementing those results. Just as important to researchers, ICTS design results can be overtaken by new technology advances before they even appear in the research literature due to the delays of academic publication.

Similarly, social and organizational environments also change rapidly. Thus, "design theories" are also perishable. That is, they are subject to change as the social reality changes. There may be, in fact, no immutable "laws of organizational design" to be discovered and codified. The significance of this observation for academic researchers is that they must constantly challenge the assumptions that have characterized research in the management disciplines. They must also recognize that creativity, change, innovation, and qualitative novelty are a significant part of the phenomena they study.

22.4.6 Artifact Utility Evaluation in DSR

Current thinking in DSR defines *utility* of an artifact as the primary research goal. In this context, the close relationship of utility to practical *usefulness* is emphasized. The choice of usefulness as the preeminent dependent variable for DSR is well established in ICTS literature (DeLone and McLean 1992, 2003). Given these strong connections to existing well-established research streams, does it even make sense to question if usefulness should *always* be our central criteria for evaluating design?

A recent research direction questions this accepted view. Gill and Hevner (2011) state that the search for the dependent variable in DSR requires some rethinking. They propose a pair of alternative dependent variables: *design fitness* and *design utility*. In the case of fitness, the focus is on its biological meaning—the ability of an entity to reproduce itself and evolve from generation to generation. In the case of utility, rather than viewing it as being roughly equivalent to usefulness, the focus is on its meaning in fields such as economics and decision sciences, where it serves as the basis for ranking decision alternatives. Naturally, usefulness plays an important role in determining both fitness and utility. Neither of these variables, however, is solely determined by usefulness. Thus, a new understanding of the relationship between the three variables via a new fitness-utility model would complement current thinking and provide important insights into the nature of DSR.

22.4.7 Invention and DSR

A genuine new invention is a difficult goal for DSR research projects and we can expect few contributions to fall in the invention quadrant. However, exploration for new ideas and artifacts should be encouraged regardless of the hurdles. Invention comes about when the existing knowledge base is insufficient for design purposes and designers must rely on intuition, experience, and trial-and-error methods. A constructed artifact embodies the designer's knowledge of the problem and solution. In new and emerging applications of technology, the artifact itself represents an experiment. In its execution, we learn about the nature of the problem, the environment, and the possible solutions—hence the importance of developing and implementing prototype artifacts (Newell and Simon 1976). Thus, editors and reviewers should be more open to claims of "newness" in regard to problem and solution domains. However, rigorous surveys of existing knowledge bases must be done before any claims of inventions in DSR are made.

Identifying Opportunities for IT-Enabled Organizational Change

Matti Rossi
Aalto University School of Business

Juho Lindman
Hanken School of Economics

23.1 Introduction

Process modeling and designing transformative information technology (IT) were once seen as panacea for implementing changes in organizations when they modernize their operations (Williams, 1967). Manager's role was seen primarily as modeling of processes and creating interventions to systems that resulted in measurable impact (Hammer and Champy, 1993) or finding ways to increase the amount and transformative capability of IT in the organization (Venkatraman, 1994). The problems of failed and misused IT were identified as a strategic management issue, including issues such as poor alignment between business strategy, IT strategy, organizational infrastructure and processes, and IT infrastructure and processes (Henderson and Venkatraman, 1993). However, the causal link often implied in these theories that explains coexistence of IT implementations and organizational change is deeply problematic to the degree that the direction of the causal link and the identities of the actors are at times questioned (Markus and Robey, 1988). One way of addressing this issue is the situational practice lens, which studies the transformation of IT and organizational structure and practice together as a process that involves institutional environment and thus is complex and difficult to predict (Orlikowski, 1996).

When systems have grown larger, it has become clear that many integrated enterprise systems (ESs) act more like organizational cement (Davenport, 2000b). Systems that were implemented and maintained to allow for change have actually become harnesses that slow down the change. Complex integrated systems develop institutional inertia, a legacy, on their own (Hanseth and Lyytinen, 2010). This is natural; the systems have grown so large that they are the core infrastructure of modern multinational organizations. However, organizations are facing increasing pressures for change and, thus, it is

not optimal that the main information systems are inhibitors rather than contributors to the change (Markus, 2004). This state of affairs is increasingly unsustainable, and there could be ways of changing it for the better.

Implementing change in organizations is notoriously difficult. After failed efforts for organizational change, it is not unusual to introduce a new information system as a way of introducing process changes. This is a way to externalize the organizational problems into a project, where the costs of the organizational change can be attributed to the management of the project. If this is the starting point for an IT project, the process can easily become an uphill battle. However, if the modernization of information systems is seen as and is planned to be an enabler of future change, the road ahead is simpler (Upton and Staats, 2008). Maintaining shared set of beliefs underlying the implementation project and its rationality while aiming at inclusiveness of the different interest groups in the organization is a critical issue in delivering the desired organizational change (Willis and Chiasson, 2007). Unlike in the past, most employees, customers, and business partners will be users of the corporate systems, and thus, their input on the requirements and to the organizational change is critical (Mathiassen, 2002). There are a few indicators suggesting that future users will be different in terms of skills and expectations. In general, a likely further increase in specialization and professionalization will be a reaction to the growing complexity organizations face from their internal and external stakeholders. More and more professionalization will include using specific software systems, such as human resource, customer relationship management, or supply chain management packages. Also, many future users are digital natives so that dealing with software will be natural for them (Vodanovich et al., 2010). Hence, they can be expected to not only accept but even demand for the extensive use of elaborate software systems in their work environment. At the same time, future users can be expected to be more demanding. This can become a challenge, if the systems fail to provide the promised functionality, as often seems to be the case in the early phases of any implementation process. Users may require smart—and fancy—user interfaces as consumer products feature them. Therefore, they will probably more profoundly resist against being bothered with information they do not need—or against performing steps that are redundant, meaningless, or a threat to their autonomy.

Alignment is a process where business requirements, organizational and cultural elements, and technological solutions are brought together. Conventional wisdom approached alignment and building the applications using the waterfall model: First (real world) business requirements are mapped out and then the technical solutions are designed and implemented to those problems. This might require several iterations. New approaches highlight the variety in the uses of these IT systems such as workarounds, conflicts in the requirements for the systems, and improvisation and creativity (Macredie and Sandom, 1999). Business architecture is a concept that ideally connects high-level strategy and business models to the digital execution platforms. Both practitioners (Ross et al., 2006; Upton and Staats, 2008) and researchers (Hanseth and Lyytinen, 2010) see a flexible architecture as a key enabler of change in future digital organizations.

In this chapter, we look at the ways to allow for what Markus (2004) calls technochange to happen more often. Technochange means that instead of limiting scope of change to process and technology modification, organizations should link the technical elements to the social, personal, and political aspects of the units and individuals who are undergoing the change. First, we outline ways of making the core ESs of an organization to work. Then we describe how the business architecture based on the ESs can be used to change work processes and customer facing processes through the use of mobile systems and other lighter interfaces.

23.2 Enterprise IT and Organizational Change

The relationship between IT and organizational change has been widely recognized (Boudreau and Robey, 1999). Changing roles and responsibilities or changed distribution of power, resulting from the new information system, may cause resistance to change in an organization (Markus, 1983).

Large integrated system implementations change the status quo of the target organization: Some departments and individuals gain more than others. Engaging and coordinating different individual and group interests require often subtle political maneuvering. The scoping of the project is a critical concern here: Large projects gather more inertia, and the costs of enrollment are much higher than in the smaller and more incremental projects.

ESs have been defined in many ways in prior research. We consider ESs to include the enterprise resource planning (ERP) system functions and all the other applications providing an integrated information system for most functions of a company (Davenport, 2000a). According to Davenport (Davenport, 1998), an ES seamlessly integrates all the information flowing through the company (e.g., financial, accounting, human resources, supply chain management, and customer information) into a centralized database. Thus, an ES provides a technology platform that enables a company to integrate and coordinate business processes and to share information across the company. ESs also allow allocation and coordination of resources across time zones and geographical locations while keeping the data available and centralized. In Zuboff's words, "activities, events, and objects are translated into and made visible by information" (Zuboff, 1988). Thus, an ES aims to organize information processing in an organization around standardized processes or best practices and offers uniform tools to access the data (Davenport, 1998). Best of breed solutions may also enforce standardized processes that come directly from the vendor company. Informational visibility of the objects also changes organizational information accessibility, if it is used, for example, in performance monitoring.

Although ESs are seen to increase organizational efficiency, this depends on the context and whether the associated changes in business processes can be achieved. Light et al. (2001) argue that the benefits may realize only after some advanced modules, such as customer resource management, are implemented. Organizational change either before or during the implementation is seen as beneficial for the implementation (Davenport et al., 2004). In this chapter, we view ES in use as a change agent and a way of enforcing the changed practices.

During a company's organizational transformation, ESs may adopt different roles. ES should become the digital infrastructure (or architecture) of the company (Tilson et al., 2010) and allow for changes to strategy and organizational structure. In the following section, we assume that ES is developed through an open architecture, which allows external systems to use the ES data and processes.

23.3 How to Seek for Opportunities?

Markus states that "a reason that managers use IT to drive organizational change is that starting major cross-functional changes without an IT focus does not work in many organizational cultures" (Markus, 2004). Tools for cultural change [traditionally called critical success factors (Al-Mashari et al., 2003)] include senior management support, user involvement in system design, breaking of departmental silos, and improve staff motivation and managerial decision making (Jackson and Philip, 2010). These kinds of tactics are by themselves not enough (ibid), but they should be both accompanied with technological change and ongoing attention to issues that typically emerge when cultural and technological changes occur.

In what follows, we will note some interesting general technological developments that we consider important. We complete the chapter with specific examples of the interplay of organizations and two technological changes taking place due to (1) increased mobility and (2) increased openness.

Radio frequency identification tags (Curtin et al., 2007; Weinstein, 2005) provide a new means for data retrieval and storage. Their main usage is related to surveillance and identification of items remotely from a short range. The price of sensors and tags has gone down, and their usage for different kinds of automated tracking scenarios has increased vastly. Examples include integrated tasks such as workplace monitoring (Kaupins and Minch, 2005), supply chain management (Chow et al., 2006), or parcel tracking. New electronic and mobile integrated payment systems offer more real-time transactions and monitoring of funds and investments (Mallat et al., 2004, 2009). In addition, new devices

provide a means for secure physical identification, which then enables organizations and individual's ways to conduct legal transactions (e.g., payment or electronic signature), which are not constrained by the paper trail. Cloud-based access to organizations resources calls into question conventional truths about control and management of organizations databases as well as their content and different kinds of digital assets.

23.4 Possibilities Based on Specific New Technologies

In this section, we briefly outline the possibilities of two specific technologies to act as change agents. First is a process technology, mobile information systems, and second is what is called the steam engine of the twenty-first century, open data. Both have possibilities for radically altering the current ways of working in private and public enterprises and affecting the ways that people work and use services.

23.4.1 Mobile Systems as Change Agents

One clear possibility for searching new opportunities is through augmenting ES with mobile technology. Mobile technologies are expected to enhance business efficiency by distributing information to the workforce and by offering new communication channels with customers (Leung and Antypas, 2001). In earlier studies, mobile applications have been seen suitable for truck drivers, service teams, traveling salesmen, and so forth (Berger et al., 2002; Bruegge and Bennington, 1995). There are, however, limitations in each case, related to the technology-based change. These limitations are resources, timetable, the urgency of the need, current infrastructure, such as IT equipment and software, development of mobile technology, the pace of the change, organizational culture, and, in particular, old habits and resistance to change. Furthermore, mobile fieldwork makes it challenging for management to coordinate sales people, particularly in terms of information transfer (Watson-Manheim and Bélanger, 2002). Recent advances in mobile technology, such as LTE networks and handheld tablet computers utilizing these networks, are rapidly expanding the use of mobile devices in different types of enterprises. Examples of uses that have reached a critical mass are the aforementioned mobile payments, the use of tablets in cockpit (Murphy, 2011), and health care (Basole et al., 2012).

23.4.2 Open Data as a Change Agent

Increased availability of data about organizations and society holds untapped potential for change (Shadbolt et al., 2006). Open data refer to a specific subset of all data—data that are "openly" made available. Usually created by various levels of government, open data are based on the ideas that if more data are made available, better and more transparent decisions are made in organizations. Open data are defined as follows: "A piece of content or data is open if anyone is free to use, reuse, and redistribute it—subject only, at most, to the requirement to attribute and/or share-alike." (http://opendefinition.org/). The idea is that the organization, which releases the data, intends that the data are used as a basis for new applications and services. The ideology underlying open data is similar to that of open source (Lindman and Tammisto, 2011). Open source is about the applications in a society, open data are about data. These two phenomena also have strong links historically, culturally, and technically, although many open data activists do not endorse this comparison. Work of Kuk and Davies (2011) identifies several artifacts and stages in the service development, which builds on open data sets.

Now let's turn from viewing the organizations as a consumer of data and focus on organizations as a source of open data. *Private open data* means data collected and owned by a commercial actor that are made available for reuse over the Internet. What could these type of data be about? The objects described in the data sets are different but can be divided into (1) data about the organization in question and (2) data about the environment of the organization. The question becomes important in the discussion about what data sets are created and how. When we take the service design perspective, we need to know

what the benefits offered by opening the data to its ultimate users are. This, in turn, requires theoretical understanding of the relation between the digital data artifacts and organizations. Especially of interest here are the organizational goals that lead to opening up the datasets.

Another concern is the tension between organizational requirements of data and the interests and claims to the authority of individual users. This means that the increased openness of data challenges the current ways of controlling information resources. The availability of more an open digital archive of (organizational) transactions makes certain issues more visible and hides others [for a thorough discussion, see Marton (2011)]. Radical redistribution of organizational knowledge might occur if the digital trail of the actors is available to more users in an organization. This redistribution has its winners and losers but could in correct circumstances result in more transparent decision making and thus better or at least more deliberative decisions. Unfortunately, it could also result in more technological surveillance (Fuchs, 2011; Zuboff, 1988). Surveillance theory ties in the organizational authority structures, new competence requirements, and the digital trail of the actors archived in the databases. One of the main sources of this information would be accounting systems, data warehouses, and integrated ERP solutions (Zuboff, 1988).

Another epistemological question is related to the malleability of the data. How do we know whether the data we are relying are trustworthy? One answer to this question is to revert to the old open source saying "more eyeballs make bugs shallow" and rely on the wisdom of the crowds. Additionally, if the processes that bring about the data are transparent, the likelihood of the data also being valid and trustworthy increases.

Data are also an interesting kind of digital object in its own right as it represents something, but often this representation is not trivial. Data do not necessarily include a description of a process by which they came about, but their provenance is still tied to the data gathering, storage system, retrieval classification, and organizational usage. One industry facing substantial changes in regard to data management is the newspaper media.

23.4.3 Concrete Case Example: Augmenting ERP with Mobile Technology

In an action research study (Rossi et al., 2007), we studied the re-engineering of field sales processes of Amer, a Finnish tobacco company operating in Estonia until the end of 2004, when the change of the owner of Amer's business unit in Estonia took place. The importance of mobilizing the workforce, adopting mobile technologies, and providing mobile information access integrated into the enterprise IT systems as well as applications for field force professionals is highlighted by Lyytinen and Yoo (2002), who outline the evolution from traditional enterprise IT toward ubiquitous IT. The case company employed mobile field sales personnel that worked in remote locations most of the time; some of them needed to come to the central office only once in a month.

To enhance customer support, the company decided to launch a project to solve the problems of work and document flows and to empower the field sales staff. It was decided early on that the work processes on the field sales have to be modeled so that the processes could be supported by advanced IT. The main objective was to create a solution to document production in the field. This would result in a faster document flow while allowing the dispersion of work in terms of time and place. The initial approach taken was based on process re-engineering utilizing mobile communications technologies. There were two main reasons for this: First, the mobility of the workers and the need to cut down the document cycles forced the company to seek solutions that can be used anywhere. Second, a real-time process was seen essential to overcome the process inefficiencies that interfered with client service.

The goal of this project was to streamline and shorten the ordering and billing cycles. Efficiency gains were sought through recording information at its source and delivering it immediately to the back-office systems of the company. The starting point was to be able to use mobile technologies by mobile employees in such a way that the data created in the field could be entered in real time to the ERP system of the company, thus replacing several error-prone manual steps with one data entry procedure.

23.4.3.1 The Case Company: Amer Tobacco

Amer Tobacco AS (hereinafter Amer) was a part of Amer Tobacco Ltd. that belonged to the Finnish concern Amer Group until the end of 2004. Amer had started its operations in Estonia in 1995, and it conducted its business through active field sales and deliveries of products to retailers and wholesalers.

Amer's clients in Estonia were small retail food businesses. Forty percent of sales were generated from wholesale and contract customers who were administered by key account managers. The rest (60%) of sales were generated from field sales. Amer's field sales personnel handled sales to stores, kiosks, and restaurants. The company served altogether around 1500 customers, two-thirds of which by the field sales representatives. For the most important store chains, deliveries were made from the central warehouse.

The operations of Amer were organized into business functions. Key business functions included sales, marketing, administration, and warehousing. Efforts had been made to simplify administration to the largest possible degree, and the same staff members often carried out several phases in different processes.

All Amer's operations were managed by an ERP system called Hansa. The Hansa modules in use were accounting, inventory, ledgers, purchase and sales orders, invoicing and cash register, and client management. Centralized data management in the Hansa system made working regimes more structured and reporting more standardized and thus more unambiguous. Extra reporting for the management purposes was prepared mainly with Microsoft's Office tools.

23.4.3.2 Old Field Sales Processes

All business processes in Amer evolved around the customer and customer service teams, to which the field sales representatives belonged. These field sales representatives operated in different parts of Estonia and were responsible for their clientele in the respective areas. They visited 15–25 customers a day, negotiated with customers with the objective of getting an immediate order, delivered the products to the customer, and invoiced the sale. The functions of the field sales representatives included keeping record of receivables from his or her customers. In case there had not been a payment, the objective of the visit was no longer sales, but collection of receivables.

Ordering, invoicing, and delivery from a van took place during the same customer contact. Invoicing was completed by writing an invoice by hand on a carbon copy paper pad. After closing the deals, the sales representatives sent invoices and other documents required for reporting purposes to the Amer office by mail once or twice a week. Invoicing data were handled and entered in the office to an ERP system by the office secretary.

23.4.3.3 Problems with the Old Processes

The main problem of the old order-and-delivery process was its long flow time. Firstly, because of the delay between the date of the invoice and the date it was entered to the ERP system, and because, for several clients, the payment term was short (typically 7 days), the company had often received payments before the invoice was even entered to the system. Collection of overdue receivables could start only after the keying in into the system was completed. A delay in the collection could further slow down the continuous business with the same customer, thus weakening the quality of customer service.

Secondly, entering sales information was time-consuming for both the field sales representatives as well as for the office staff. Furthermore, the same sales information was recorded twice: First, a sales representative issued a hand-written receipt to the customer and then, an office employee entered the information in the system. Entering the same data twice also created increased possibilities for errors. Delivering these hand-written receipts to the office created another factor weakening the flow. The fact that the receipts were delivered to the office only twice a week created a significant delay in recording information.

The process flow regularly contained operating irregularities that weakened the level of service quality. For instance, sales needed to be put on hold while taking inventory to ensure validity of the results,

and reporting was even more delayed if the paper receipts were lost in transportation. It was not unusual for the check pads to be late from the printing house, and invoicing was interrupted. In the course of time, additional activities had been developed to correct these irregularities. An example of this was checking information on customer payments. Because of a delay in recording, sales representatives were forced to check payment information directly from the customer.

After receiving the invoice data from sales representatives, an office staff member entered it to the ERP system as a collection run. The same person also handled possible error messages before the confirmation run, after which the stock inventory information was updated in the EPR system.

23.4.3.4 Developing a Mobile Field Sales System

The solution needed middleware for efficient data transfer between the mobile terminals and the Amer Estonia office in Tallinn. Gateway software supplied by Klinkmann Ltd. and a GSM modem that connected the office PC into the GSM network and the terminal devices of sales representatives were installed. PC that handles data communication at the office was connected to the company's IT network and the ERP package.

The selected GSM control software was compatible with Microsoft Excel, which served as a bridge to the ERP system. The bridge allowed automatic securing of wireless communication messages (sent/received) and indexing of messages, which allowed handling of messages in case of operational malfunctions. If and when there were changes in the order–delivery process or its functions, configurations to the solution would have been relatively easy to complete.

23.4.3.5 The Mobile Sales Solution

The chosen mobile terminals, Nokia Communicators (NCs), include a standard user interface based on Excel. NCs were chosen over portable computers because of their smaller size and corresponding significantly better portability, as well as for their greater battery capacity.

For enquiries and orders, the NC had a set of Excel-based forms to be filled out by the sales representatives. After printing an invoice, the field sales representative sent a copy of it to the main office. Control gateway software transferred the Excel spreadsheet data as SMS messages over the GSM network. Only the data that had been changed was transferred, limiting the length and number of the SMS messages. To keep the message short, the SMS message included only coded information: client number, invoice number, price list code, date, payment time, product code and quantity, and the sender's ID code. This was important for keeping the costs down. The server software combined the individual messages and updated the predefined cells in the Excel spreadsheet with data received. Information from the Excel spreadsheets was then imported into Amer's ERP system.

In the new system, during a customer sales process, the order could be stored directly on the NC terminal of the field sales representative, eliminating the need to make notes separately on a paper. Changing invoicing details was also made simpler and quicker. Dispatch of invoicing information remained double: After the invoice was printed out, the invoice data was sent to the office in real time as an SMS message through the mobile GSM network. The printed invoice document signed by the customer, however, was still sent by mail to the office afterward, as a delivery confirmation.

23.4.3.6 Business Impacts of the Project

In terms of event flow, the new and old processes were very similar. As the modifications in the process flow were not radical, the change was well accepted and employed by the staff quickly. This made it possible to complete the pilot project in the planned schedule of 5 months. The implemented IT solution removed a lot of inefficient and overlapping functions.

The new solution significantly reduced document handling at the back-office (see Table 23.1). The only remaining manual work was archiving, since the invoice information was entered directly in real time by the mobile users and transferred to the back-end systems automatically. This significantly reduced typing errors as well as the amount of clerical work needed. Another enhancement was the single direction of the

TABLE 23.1 Measures of the Project Success

Measure	Before	After
Invoice verification	7–9 days	1 day
Billing cycle	Week	3 days

document flow. Even though invoice copies still needed to be sent to the office, the sales representatives now had more flexibility in choosing the most convenient time of a week for the delivery. The information about the orders and invoices was entered into the ERP system in real time. Thus, the sales and stock reports were updated practically in real time, and the representatives could review the regional stock levels anytime throughout the day. Furthermore, since the office assistants no longer needed to manually enter the data, they could concentrate their efforts in collection of receivables as well as other duties.

23.4.3.7 Evaluation and Learning from the Project

The order–delivery process was the most important and critical process for the case company. The reported process re-engineering project took into account process risks, and the old model was maintained in case the results of the re-engineering would turn out to be unsuccessful. The focus in the project was solely on increasing the efficiency of invoice documentation, but it also enhanced the process transparency and overall performance. This is largely in line with what (Schierholz et al., 2007) propose with their method for mobilization of CRM: focus on the analyses of business processes and the corporate benefits, which can be realized by their mobilization.

23.4.3.8 Lessons Learned Regarding Process Change

The new process model improved the level of customer service quite noticeably. Credit monitoring in real time reduced credit risk, because the field sales representatives now received payment information on real time, making sure that all customer visits focused on sales.

In addition, the new process and solution increased the efficiency of collecting receivables and handling temporary interruptions in deliveries. The increase in the quality of process output reduced the need of phone inquiries for information from the customers and field sales representatives on payment details. Stock management and all sales information in the ERP system were available in real time. Freeing working time from paperwork routines and clarification of errors was seen as a factor that motivated both the field personnel as well as the office staff.

Mobile technology together with process re-engineering brought noticeable efficiency gains to Amer, both in terms of significantly improved process flow time and reduced delay time. Mobility also enabled true independence from time and place: A field sales representative was now able to send the documentation immediately after completing sales deal, irrespective of his or her location and office hours. It is notable that the changes to the processes were designed to cause minimal overhead and learning curve to the users. We believe that this made the change resistance far easier to handle and minimized implementation risks. In this case, we can claim that the process can be made simpler and less error prone and at the same time customer service can be enhanced.

In several cases, companies have integrated wireless technology with their business processes in an attempt to enhance efficiency and improve service lead times. This can be argued to be a profound change into how companies use IT and change into more service oriented enterprises (Grönroos, 2008).

23.5 Conclusion and Implications

In this chapter, we identified the possibilities IT creates in organizational transformation processes. It was found that IT has two roles in the transformation: it helps to implement change into the core operations of the company through ESs and architecture, and it helps by allowing future change through improvising at the edges of the systems.

23.5.1 Theoretical Implications

ESs play a dual role of enabling the change and reinforcing the new organizational structures, and thus there is a reciprocal relationship between the IT and the organizational change (Mattila et al., 2011). While the IT enables and helps sustain the change, it is also getting shaped by the organizational change, and in some cases, it is an inhibitor of change (Alter, 1999).

The advent of mobile enterprise and open data challenge the dominance of monolithic ESs. This calls for research on how more agile enterprises can be supported by more agile enterprise architectures and how we change from process centric to connection and data centric enterprise architectures. Organizational theory has been struggling to better capture the role of the new availability of information and system artifacts in organizations concerning organizations strategies, boundaries, environment, etc.

23.5.2 Practical Implications

ESs should be used in such a way that they help the change process and create new business opportunities instead of hindering them. The management expectation that systems could act as change agents is theoretically problematic and practically much challenged. For the change to succeed, knowledge workers need to understand and be well motivated to use the system according to the new processes. If the system does not support the users in their daily routines, it is unlikely they will utilize it due to this task misfit (Markus, 2004), thus rendering the sought management coordination obsolete.

23.5.3 Future Directions

IT developments are often difficult to forecast. The social and institutional implications of the IT technologies are even more elusive. However, several continuing trends seem prevalent. Trends such as the increased computational capabilities, improvements of sensor technologies, and communications infrastructure open up organizations to further increasing virtualization of workplace, changing practices of knowledge work, rapid internalization of certain activities, and in general, acquisition of contribution outside the traditional institutional boundaries of organizations. These advances require new designs for systems and probably also more modular architectures of the new systems (Ross et al., 2006). We foresee that the problems caused by complexity of these systems and marketplace operations of the IT system vendors likely create risks of more nonfunctional, non-compliant, and non-interoperable systems. Larger patterns in society's infrastructures such as the emergence of social networking sites, for example, Facebook, challenge and offer new possibilities for these systems. The immediate impact of, for example, enterprise social networking to system design, support, and work practice seems difficult to foresee, but we argue that smaller systems working together is a more likely scenario than ever larger monolithic systems.

Deconstructing Enterprise Systems: Emerging Trends in the Next Generation of ES Applications

Paul Devadoss
Lancaster University

24.1 Introduction

Enterprise systems (ESs) are packaged systems serving a wide range of functions in organizations. Such enterprise-wide systems are designed to achieve scalable intra-unit integration and rapid dissemination of information (Ross and Vitale, 2000). ES evolved from inventory control (IC) and materials requirement planning since the 1970s and 1980s to their current potentially all-encompassing nature in business information systems (IS). ESs now represent an entire category of IS that has gained momentum and widespread use since the 1990s.

ES applications are industry-specific, customizable software packages that integrate information and business processes in organizations (Markus and Tanis, 2000; Rosemann and Watson, 2002). ESs are encoded with "best practices" in organizational business processes. "Best practices" are identified through academic research on industry practices and shared understanding of acceptable efficient processes among practitioners. In any ES implementation, organizations may choose a single package or a combination of ES modules that suit their particular functional needs from several packages and implement them accordingly. They may also need to implement middleware (applications that bridge across software systems). ES packages are often customized, although extensive customization is inadvisable due to cost, time, and complexity (Markus and Tanis, 2000). In addition, since they are modeled after "best practices," modification and customization would seem unnecessary and detrimental. Companies often view such ES as a panacea for fragmented information, incompatible legacy systems, and outdated inefficient processes.

Organizations spent about USD $45.5 billion on ES in 2011 (Forrester Research, 2011). IT spend specifically in this segment has grown at about 11% over the past 6 years. However, despite extensive use in several industries, ES implementation is still regarded as a highly risky process. It is often reported that a large number of ES projects fall short of targets in terms of costs, time, or functionality (Esteves and Bohorquez, 2007). Despite the intuitively obvious benefits of ES to an organization, there are several aspects of implementation and use of ES that can and have gone wrong (e.g., Scott and Vessey, 2002). Several studies on ES implementations have identified project failures and difficulties in ES implementation (Esteves and Bohorquez, 2007). Such dramatic and, often public, failures have perpetuated a lingering message of difficulty with such systems. Financial analyses do, however, suggest that there are positive returns from ES-related investments if an organization is willing to work at it (e.g., Anderson et al., 2003). Due to the scope, complexity, and risks associated with ES, they are fundamentally different from other IS, requiring significant organizational investments in terms of technology, time, training, and human resources.

In this chapter, we look at the structure and implementation of ES in organizations to understand the nature of business processes and their reflection in ES. The chapter also looks at some modern developments in IT to suggest future directions for enterprise wide computing applications.

24.2 ES Components and Infrastructure

ESs have evolved from internal standard IC packages to include material requirements planning (MRP) and manufacturing resource planning in the late 1980s. They have since grown to include other enterprise processes, primarily classified as finance and control, materials management, sales and distribution, and human resource management. Several other fundamental organizational functions have since been added, including some add-on modules that have now become critical due to increased modern day usage, such as business intelligence. Early forms of these systems were often locally developed or assembled through a combination of developed and packaged systems. Currently, ESs are typically packaged, off-the-shelf software solutions that embed industry-wide best practices to integrate business functions and processes into a single, comprehensive framework (Markus and Tanis, 2000).

The size and complexity of ESs have meant that implementations of such systems are extremely complex, requiring a blend of technical and functional expertise (Gallagher et al., 2012). They are difficult to deploy requiring extensive resources and are complex to use (Devadoss and Pan, 2007). Implementation projects require extensive organizational participation and clearly defined goals with adequate resources to successfully complete a project. Consequently, ES literature has accumulated a large number of studies on implementation. Such studies have identified ES selection frameworks, project management techniques, success and failure factors, and lifecycle management frameworks, among several other aspects of ES implementation (Esteves and Bohorquez, 2007).

Organizations face several risks during ES implementation. Such projects often run behind schedule, fail to deliver on project goals, or over-run on costs. Organizations also potentially experience a period of low productivity during and immediately after ES implementations due to resources absorbed by implementation projects. Some ill-timed projects may even contribute to bankrupting an organization (Hitt et al., 2002; Scott and Vessey, 2002). Much of the underestimation of ES implementation complexities may perhaps be attributed to a failure in recognizing the significant differences between ES and traditional IS (Markus and Tanis, 2000).

ESs, by design, support process-oriented view of the enterprise and its business functions (Nah and Lau, 2001). They streamline the flow of information across traditional business functions by utilizing a common IT infrastructure (Newell et al., 2003). Traditional IS generally support functional units independently, potentially with disparate platforms, and, hence, are not integrated. If they are to be integrated, they may require another layer of software to interpret among various systems (known as middleware). In contrast, ESs offer tight interdependencies among a firm's functional units, bringing

together all activities so that they operate as a whole with real-time data (Klaus et al., 2000; O'Leary, 2000; Robinson and Wilson, 2001; Ross and Vitale, 2000).

Due to the integrative nature of ES, implementing ES is a complex task with complications and risks that go beyond those associated with traditional IS (Bunker, 2000; Markus and Tanis, 2000; Sumner, 2000). For instance, integration means standardization of data across functional units. Furthermore, an ES imposes "its own logic on a company's strategy, organization and culture" (Davenport, 1998, p. 121). Hence, ES users must not only be trained to use the software but also educated on the overall logic of the system. Due to such complexity, ES implementations often end up late, over budget, or in failure (Davenport, 1998; Gibson et al., 1999; Scott and Vessey, 2000). Furthermore, as new business models evolve in modern globalized marketplaces, ESs evolve to include more functions and processes among their modules, making such systems far more complex.

In their approach, ESs have been closely linked with business process redesign, although there is some debate as to their sequence in implementation, thus affecting users with process and system changes (Bancroft et al., 1998; Esteves et al., 2002). Processes in ES, by virtue of the best practices embedded in them, are often potentially in conflict with, or, at best, different from an organization's existing practices (Krumbholz and Maiden, 2001). This conflict can be resolved either by tailoring the enterprise resource planning (ERP) software to suit the existing business processes or by reengineering the organization's processes to adopt best practices in the software, with minimal customization of the latter (Al-Mudimigh et al., 2001). Minimal customization is often considered beneficial to avoid high cost of customization and complexity (Bancroft et al., 1998; Holland et al., 1999). Recent technical developments such as componentization and enterprise frameworks are attempts to mask some of this complexity by allowing ES to be tailored across different areas of the business in a more effective manner (Fan et al., 2000). However, modern ESs have attempted to simplify implementation by further tightly integrating modules. Such efforts reduce implementation time, but hide greater complexity should an organization pursue customization. A significant proportion of ES projects also fail due to an underestimation of changes necessary in the organization (Appleton, 1997).

According to Davenport (2000), reengineering results in changes in an organization's strategy, structure, and culture, and the behavior of its workers. Davenport (1998) states that such changes tend to be paradoxical: ERP promotes more flexible and flatter organizations through increased information sharing, while centralization of control over such information and standardization of processes (according to the software) tend to promote command-and-control organizational structures that stifle innovation. ESs thus impact employee roles by rendering tasks more broad-based, necessitating a shift in the nature of skills and knowledge possessed by the individual (Davenport, 2000). Some studies illustrate how individual knowledge becomes more divergent due to ES as subject specialists need to know more about other business areas (Baskerville et al., 2000; Sia et al., 2002).

Despite implementation complexity, efficiency is a major motivation for ES use (Davenport, 1998; Nah and Lau, 2001; Newell et al., 2003). ESs are expected to reduce operating costs and improve productivity through greater information exchange and redesign of business processes. Another stream of literature reports that primary incentives for an organization should be strategic in nature, providing competitive advantage (e.g., Davenport, 2000). Other motivations include the organizational need for a common technology platform, improved data visibility, enhanced decision-making capabilities, and better customer responsiveness through unified view of the organization (Markus and Tanis, 2000; Ross and Vitale, 2000). Visibility of standardized real-time data across the entire organization is a significant advantage offered by ES.

A smaller proportion of ES studies have examined issues in the use of ES. Yet, it is during use that many ES problems are manifested, even if they might have originated from implementation (Markus and Tanis, 2000). During implementation, initial patterns of usage emerge. As early patterns of usage are known to congeal and become resistant to change (Tyre and Orliwkoski, 1994), they form an interesting subject for researchers seeking to understand ES use in general. Typical issues around ES use relate to lack of visibility to understand purpose of data collected in processes, complexity of systems, or lack of awareness or participation in ES implementation, consequently leading to user apathy (Devadoss and Pan, 2007).

In the context of earlier discussions in literature, this chapter shall deliberately avoid discussions that dominate ES literature, such as ES implementation projects and success/failure factors.

Instead, this chapter will discuss three key aspects of ES that are necessary to understand the nature of ES and their impact on organizations. First, we begin by understanding ES design based on business processes and consequent issues in implementation projects. The next section will follow up with a discussion on participants in an ES project and the nature of ES market ecosystem. This section further identifies some issues that impact the deployment of such complex IS in organizations. Finally, with our understanding of design problems in the existing generation of ES, we look at modern technologies that are likely to address issues identified in these discussions and influence the next generation of ES. We then discuss some implications for research and practice.

Several discussions on ES have often focused on outcomes observed during and post-implementation of such systems. However, it is necessary to deconstruct the underlying design of ES to understand the source of its complexity and the nature of issues that appear during implementation projects. Toward this purpose, in the next section, we begin by understanding how work is structured as a process and its consequent appearance in IS as discrete tasks. This section also lays the foundation for our understanding of business processes as incomplete representation of work in organizations.

24.3 Understanding Business Processes (or Deconstructing ES)

ESs are designed around what is recognized as "best practices" in the industry and academia to perform business tasks. It relies on users and their interaction with inscribed business processes within organizations. Consequently, we begin by understanding the nature of tasks in organizations. While tasks are represented through discrete, logical business procedures, the execution of a task entails much more than just a series of steps, within or outside a software system.

The guiding influences of Frederick Taylor's (1911) ideas are evident in the modern definition of a business process. Taylor's ideas suggested developing scientific methods for each stage of a work process and training workers in each of these stages to achieve a completed task with the requisite skill. Davenport and Short (1990, p. 12) define a business process as "the logical organization of people, materials, energy, equipment, and procedures into work activities designed to produce a specified end result (work product)." They further state that "A set of processes forms a business system – the way in which a business unit, or a collection of units, carries out its business." In this view, an organization is defined as a collection of externalized business processes, which are executed in order to reach predefined organizational goals.

Suchman (1983, p. 321) notably discusses the "general relationship of any normative rules to the actual occasions of their use." This view suggests that executing any business process requires some additional and possibly significant work, in order to produce a procedure that "works"—something that is seen as meaningful and skilled by both employees and their customers. This work (of situating normative rules in actual use) involves selecting appropriate procedures and making sense of them in the organizational context. "Practical action," as Suchman calls it, refers to the "work of finding the meaning of organizational plans in actual cases" (Suchman, 1983, p. 321). Her "practical action" provides an alternate conceptualization of a business process, with a number of important implications for ES implementation and business process design.

The modern definition of a business process often excludes the important aspect of business process construction and execution in an organization—"practical action." We consider this view of practical action a direct challenge to the current view of ES implementation and business process. At a minimum, Suchman's (1983) "practical action" expands our view to the numerous and potentially infinite variety of activities beyond the discrete steps in executing a task. The focus on ES implementation and the best practices represented ostensively in an ES distracts and detracts from this important organizational and social reality of situating a process in use.

Related to this challenge, other researchers have explored the importance and primacy of "practical action" in organizational life. One such perspective is "sensemaking," introduced by Weick (1995). These two ideas suggest that people make sense of various organizational inputs in an open system in order to create organizing order (Weick et al., 2005). These individuals then make sense of tasks, and resources available to them, and such sensemaking informs their action.

Discussing sensemaking in the context of pervasive electronic contexts in organizations, Weick (1985) suggests that electronic data force users to abandon social cues that preserve properties of events, since such social cues are not captured electronically. He argues that human operators benefit from their ability to step outside a situation to make sense of any set of circumstances. Human reliance on electronic terminal affects this ability to step outside a situation and constrains them by reducing their ability to comprehend the information in its entirety. There are several reasons that such information conveyed through electronic terminals is constrained (Weick, 1985). These factors constraining human cognition of information represented in electronic screens are also reflected in modern ES, centralizing control and reducing user access to the "bigger picture" for data relevant to their business processes (Devadoss and Pan, 2007). As a result, due to sheer inability to convey comprehensive information through electronic screens, sensemaking often suffers with consequent failures within organizations. Narrow focus on individual business processes without making sense of the large organizational issues can also lead to failure of the organization as a whole (Devadoss and Pan, 2007).

Central to sensemaking (in the context of using IS) is that people need to make sense of a situation beyond the limitations of the electronic representation of the data. The current influence of ES thinking about business processes, however, falls short in recognizing a need for sensemaking. A reformed view would argue that technologies might help to trigger sensemaking by users (Griffith, 1999). Such a view would require organizations to provide users with the resources to act on information in a meaningful way. This is in contrast to the current generation of ES that are often rigid systems that often confine users' role even within a particular business process.

24.3.1 Representing Business Processes in ES

ES can be distinguished from other information technologies, based on their highly integrated and packaged nature (Devadoss and Pan, 2007). ES imposes a particular informational logic on the organization (Davenport, 1998). Furthermore, such highly integrated technologies can impose restrictions on their interpretive flexibility during use as well (Devadoss and Pan, 2007). Complexity of ES can also serve to unquestioningly preserve institutional influences (Gosain, 2004). Consequently, ES implementation and use has often been a mindless instead of a "mindful" choice grounded in the organizational context (Swanson and Ramiller, 2004).

Despite extensive developments in ES since its MRP roots, ESs suffer the same limitations as any other IS: they can only represent an abstraction of the continuously changing needs of an organization (Hirschheim et al., 1995). Even as memory systems, ES can only capture a part of the knowledge of tasks embedded in the system (Stijn and Wensley, 2001). Changing the organization to suit the system or customizing the system to the organization may address such knowledge gaps (Stijn and Wensley, 2001).

Given the complexity of ES and their impact on constraining human action in an organization (e.g., Gosain, 2004), the task-technology fit of ES is an issue of importance (Gattiker and Goodhue, 2004). Bridging this gap too appears to be down to either of two options: change the system or change practice, and in some circumstances, both these options may be impossible (Gattiker and Goodhue, 2004).

The essence of the earlier discussion in terms of tasks embedded in ES brings us back to our discussions of "practical action" and the "performative" aspect of routines. Pervasive adoption of IS designed on Tayloristic influences on tasks as procedural processes has led to two important outcomes. First, as a procedural workflow, business processes are meant to capture aspects (or perhaps abstractions) of task performance for various reasons such as institutional or organizational requirements. Performing a task is more about achieving a certain output rather than the means of achieving that task. In other words,

a task can be performed in more ways than one predesignated abstraction of work, and the accomplishment of that task is more important than ensuring repetitive completion of individual steps in a business process (as encoded in any IS). Feldman and Pentland (2003) cite the example of police routinely selecting suitable facts to fill in forms after arrests to comply with regulations.

A second important implication is individual control over data in performing a task. Individuals in an organization have lost control over how tasks are executed. In some sense, choices on how their input is processed have been predetermined. In the case of ES, such predetermination is most likely to have occurred outside the organizational context (Gosain, 2004). In the case of ESs that do closely suit some tasks, other tasks in the same system are at risk of not suiting an organization completely (or at all). Such predetermined design and implementation leads to lack of visibility and lack of control over data in organizations using ES, leaving users finding workarounds that may even exclude the ES (Robey et al., 2002). Such lack of control is accentuated in organizations that are functionally organized, leaving task performers few cues toward fully comprehending the data as suggested by Weick (1985). ES literature often reports on lack of visibility, and consequent disinterest among users in completing data that they do not directly rely on. Such users often have no knowledge of consequent impacts elsewhere in the interdependent systems (e.g., Eriksen et al., 1999).

In many work-related situations, with or without ES, tasks are complex and adaptable to numerous nuances in the context of use. Suchman (1983) discusses the example of an accounting department in an office, where processing invoices is not necessarily orderly in practice, though procedures cast work in orderly sequences. In another case involving ES, numerous pieces of material from a manufacturing plant were to be reused (Gattiker and Goodhue, 2004), but because each reusable piece needed a unique identification number per item in the ES, it was infeasible to use the implemented ES. Instead, employees used an Excel spreadsheet, and a clerk was added to the workforce. In this and many other situations, ESs failed to capture nuanced work practices and situations. The two examples illustrate different issues with the systems view of work that relies on sequentially accomplishing tasks and information technology support for such procedures. A Tayloristic and structured view of work common in ES implementations fails to capture the notion that "procedures is an outcome to which practitioners orient their work – it is not the work itself" (Suchman, 1983, p. 327).

Alternatively, Feldman and Pentland (2003) put forward a theory that identifies the need to discuss the knowledge of a task and the execution of the task based on routines. They define an organizational routine as "a repetitive, recognizable pattern of interdependent actions, involving multiple actors" (ibid, p. 96). Routines are often portrayed as consisting of fixed patterns. Organizational support for these patterns, for example, through ES, may result in people choosing some patterns more frequently over others. They identify two problems with routines: lack of agency and variability of routines. They proposed a theory of routine as a duality, which is defined by both the *ostensive* and *performative*. The ostensive aspect is essentially an abstraction of a routine, and is nonspecific. The performative aspect is the action taken by people performing a routine in an organization and it includes situation-specific interpretations of the rules in executing routines. Hence, the performative aspect includes the patterns of action used to accomplish a task. Consider the example of a travel itinerary to identify these two aspects of a routine. The ostensive aspect is the travel itinerary itself, listing travel "details" such as flight details and destination. The performative aspect includes the actual details of the trip, such as getting to the airport, completing related formalities, security checks, and waiting.

Like Feldman and Pentland (2003), we argue that the act of accomplishing a task in an organization involves more than following an ostensive procedure. If this were true, a business system could be reduced to a book of instructions, or perhaps a fully automated IS that would require no manual intervention. Instead, it is argued that we should look beyond these implicit and Tayloristic views of task performance as a series of steps and information in an ES and consider a business process as a performative and sensemaking act that is informed by the IS, but not restricted to it.

As a result, the representation of best practice in an ES omits the numerous forms of *practical action* required to successfully execute a specific business process. Such practical action involves all of the

expert and nuanced work required before and during the use of an ES, which invokes ostensive routines in order to satisfy a specific business need. Following that, a focus on only the IS can only be performative where human expertise is no longer required, and a rigid rule can encapsulate all performative knowledge in a rigid and singular routine. In considering all best practices as embodied in an ES, this mechanistic thinking is carried to an extreme, where the ostensive functionality in the ES is considered best practice, and all human expertise of practical action is considered idiosyncratic and haphazard.

In summary, the aforementioned discussion traces problems with ES usage to ES design as a "business system." Since tasks in an organization can be seen to have two aspects, as in the theory of routines (Feldman and Pentland, 2003), or as including "practical action" (Suchman, 1983), ESs need to be simple enough to allow flexible use of the system to empower users and account for the need for internal flexibility following external change. However, despite whatever ability ES may have to empower, it will also be down to individual intentions in allowing such empowerment, or scuttling it with more control (e.g., Sia et al., 2002).

Three key issues have been discussed in this section. Primarily, business processes are incomplete representations of work in organizations. Consequently, relying on business processes as accurate abstract representations further distances the technologies that are inscribed with these processes from the reality of task performance in an organization. Finally, this design problem manifests itself in various forms during implementation and use of ES. With this understanding, we now look at participants in an ES implementation project, and the overall ES ecosystem with its services providers.

24.4 An ERP Project and EcoSystem

ES products are an aggregation of business processes encoded in IS, as discussed earlier. Since business practices vary due to arrangements within industries of a kind, these products are differentiated primarily by industry verticals. Within each vertical, they are inscribed with options to perform similar tasks in some typical and popular methods to perform business functions in an organization. They also include a variety of business functions required within an organization. Due to advancements in technologies and programming techniques, these products are also integrated tightly across various functional components, making them easier to deploy in shorter implementation time frames. This has consequently lead to more "standard" implementations and less customization. All these developments have facilitated the growth of ES around the world in large and medium sized organizations. Large organizations have gone through several cycles of implementation and upgrades since the early years of MRP. ES providers have now expanded their reach to SMEs, providing products and solutions that address key concerns in terms of pricing and speed of deployment. This, however, does not make the process less difficult, as it involves several players who need to collaborate to successfully complete the project. In this section, we illustrate a typical ES project and the key players in the industry that provide ES-related services.

There are several discussions on implementation models and its participants (e.g., Somers and Nelson, 2004). However, consider the typical case of an organization that decides to implement an ERP system. In practice, it may need to engage a consultant to study and identify its key organizational requirements, mindful of what is offered in ERP systems in the market, and transfer knowledge to the client (Ko et al., 2005). Such requirements will reflect in the Request for Proposal (RFP) issued to vendors. The proposal is then picked up by ES package vendors and passed on to potential implementation partners. Implementation partners are companies with the expertise and required manpower to deploy ES packages from vendors. The implementation partners work along with ES vendors and respond to an organization's RFP with a suggested solution.

The solution generally identifies an ES product, modules and any customizations that may be required to implement the solution. Such responses also include suggestions and workarounds to prevent cost escalations through customizations. In typical implementations, other third-party applications may be required to deliver some of the functionality required by the client organization (Markus

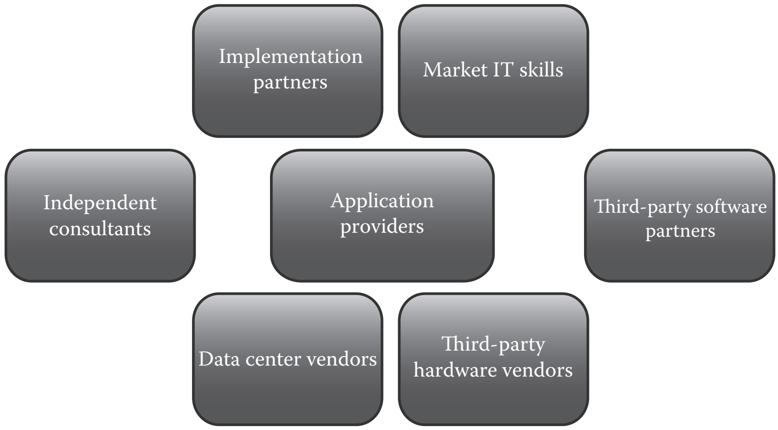

FIGURE 24.1 The enterprise systems ecosystem.

and Tanis, 2000). Implementation partners may then take on the responsibility of delivering third-party solutions as well and will manage their delivery projects. If projects are large, several implementation partners may need to be managed to deliver various segments of the project for manageability and audit.

During this phase, the client organization and potential vendors attempt to understand with some level of detail the requirements of the organization and the capabilities of the system. Considering the time and effort required to delve into details of multiple processes and identify quirks in individual systems and modules, this is often constrained to process level detail. Furthermore, such investigations are also often restricted to key processes in major functional areas (and/or functional areas of high impact as decided by the organization). In some cases, where the management considers key business processes their competitive advantage, some important business processes may be explored in minute detail along with business users. However, unless an impossible technical situation arises, implementers are often willing to find workarounds to deliver solutions to the client. The real cause for concern at this stage is the inability to pursue the suitability of any proposed solution in fine detail, and different styles of decision making (Bernroider and Koch, 2001).

The client organization then enters a period of negotiations with the vendors and implementation partners to finalize licensing costs, implementation costs, manpower requirements, project scope, time, and effort. Implementation schedules, penalties, and potential causes for concern are identified and a negotiated understanding emerges. A hardware partner is then selected to supply the hardware requirements for the chosen system. Hardware choices are made based on client organization's choice of platforms and ERP vendor/implementation partners' recommendations (Figure 24.1).

The ES product market is made of a few large vendors and several smaller vendors. Smaller product vendors specialize in specific functions in an organization. Larger providers have expanded their product offering by acquiring popular smaller systems to grow the range of functions integrated in their enterprise-wide systems. With each acquisition, larger systems have become more capable in delivering wider range of solutions to any client, while also increasing complexity in deploying solutions.

24.5 ES Implementation

A result of the high growth in the ES market is that the ecosystem for ES products is well developed with several products and services providers. Key participants in the ecosystem are vendors of ES, implementers, and consultants who assist the client organization. Since choosing and implementing a system requires appropriate level of detail, these participants are crucial to the success of any project. This is an often-neglected topic of research, though recent literature has investigated the complexity of the ecosystem and its value creation (Sarker et al., 2012).

Every organization should investigate the suitability of a product prior to implementation. However, considering the time and cost involved in investigating minute details, decisions are often made on the basis of top-level functions and business processes supported by such systems. In any typical implementation process, the organization undergoes a period where processes are identified, documented, and mapped. This process is known as blueprinting. It identifies the fundamental details such as fields, tables, and labels required to set up various processes that will be encoded for the final system.

While deploying these systems, several details are addressed by making appropriate changes to the system or the organizations business processes. Consequently, this process requires exceptional dedication and participation from users at all levels of an organization. Furthermore, each stage of implementation is interdependent on the others to effect a successful implementation (Velcu, 2010). Hence, these individual process level details are factors that affect project outcomes (Holland and Light, 1999). Users are needed to provide relevant domain expertise on processes that are being inscribed in the new system, and senior managers are required to assist in making decisions about any changes in business processes as inscribed in the new system. Incompatibility among processes in practice and processes inscribed in ERP systems can lead to delays in deployment. Often, such contradictions are left unresolved and can later lead to expensive delays in projects.

Furthermore, knowledge level of an implementation team varies according to the size and scope of the project (Ko et al., 2005). Implementation partners often vary the skill level of consultants in an implementation team to ensure balance of new and experienced consultants. The balance allows them opportunities to manage their costs and career development commitments to newer consultants in their organizations. Consequently, the composition of implementation teams and their management throughout the project can contribute to effectiveness of the implementation. Apart from these observations, implementation projects are intensive projects with several teams of diverse expertise, and hence such projects need to be managed closely to monitor and dynamically manage quality of deployment (Markus and Tanis, 2000). Inadequate experience in an implementation team can result in less optimal solutions being inscribed in the system. There are often several choices that implementers need to make in terms of choosing appropriate modules/processes/variables, etc. Experience with the system and appropriate support systems from the implementation partner are crucial to implementing optimal solutions for the client (Ko et al., 2005).

24.6 Evolving Technological Changes

ES technologies have evolved along with the progress of technologies over the past two decades. Large centralized systems delivered in cryptic terminal-based user interfaces have now migrated to reasonably informative web browser–based user interfaces. Backend technologies have become sophisticated enough to manage large volumes of data. They also include complex computing capabilities. However, the integrated nature of the system has inevitably increased the complexity in system architecture, leading to a setup that requires layers of database and applications over hardware management systems. In addition, since organizations now possess large volumes of data about their products and services, new data mining applications assist in identifying improvements and opportunities in existing business processes (Moller, 2006). Such applied usage, one of the fundamental reasons for the introduction of ES in organizations, has also benefitted from advances in technologies, such as cloud computing (Figure 24.2). Cloud computing has made it possible for organizations to deliver applications to its distributed workforce across supply chains and geographical distances (Marston et al., 2010).

Several new technological developments have an impact on modern day usage of computing within organizations, increase in use of modern computing devices has led the growth of the phenomenon known as "consumerisation," where user expectations and computing usage patterns are affected by the growth in consumer electronics (such as the use of smartphones and tablet devices influencing similar expectations in work settings). Consequently, users are now familiar with more advanced devices and applications with advanced user interfaces to accomplish work-related computing tasks, promoting

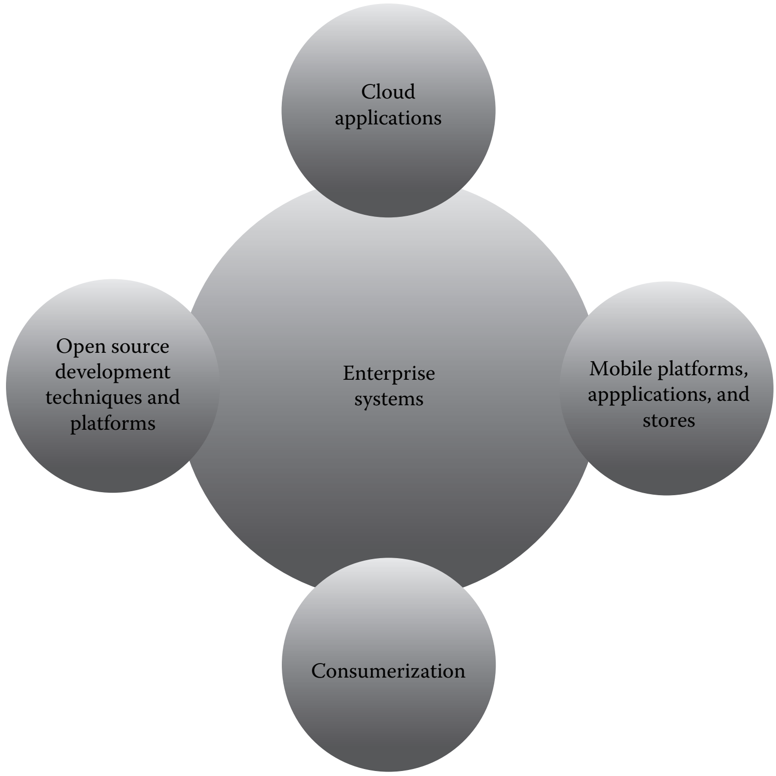

FIGURE 24.2 Erosion of traditional ES models.

enterprise mobility (Consoli, 2012). This is the opposite of what happened in the early years of computing in organizations, when computer self-efficacy was a significant factor in IT use (Agarwal and Sambamurthy, 2000). As a result, business applications now have to adapt to delivering applications over devices and platforms that users find familiar. Smart phones and tablet devices are commonplace in modern day organizations, as are "application" stores to deliver applications over these devices. Since these modern devices are smaller, with less intensive computing power, and operate on platforms that are stripped down versions of operating systems, cloud computing could become an important part of such IT infrastructure for organizations. There are now several mobile device platforms, applications, developers, and application stores (Giessmann et al., 2012).

As a consequence of the "consumerization" phenomenon, there is also a growing workforce of programmers who can deliver targeted applications that focus on specific business processes. Currently, such applications are made available in corporate private application stores for enterprise users. Such business applications on mobile platforms can interact with cloud architectures to store, retrieve, and perform complex processes outside the capabilities of such devices, thus delivering complex information processing support for organizational processes (Giessmann et al., 2012). As a result of such applications and platforms, two key issues are fast gaining traction in corporate use: focused business applications that deliver specific functionality, and abundance of low cost programming solutions for organizations.

The tremendous growth in such technical capabilities could lead to the availability of greater variety of applications that can together deliver important functions for any organization. This will result in the ability to design and develop third-party solutions (or even open source solutions) that can be deployed without the complexity of implementing expensive and time consuming and complex integrated ES. A "swarm" of such applications can replace our current understanding of ES.

Enterprise application stores for modern application platforms are now available in large numbers (Giessmann, 2012). However, further research is necessary to identify application requirements engineering techniques, and coordination mechanisms among these process focused applications to integrate and deliver functionality in organizational settings. Since large organizations often operate their own stores, they need to evolve mechanisms for coherent requirements engineering and development. Third-party stores for smaller organizations may need other protocols to coordinate development and delivery of applications. This exciting new development in ES requires significant research from IS researchers to identify organizational practices and mechanisms for absorbing these stores into organizational use.

24.7 Key Issues Affecting Current ES

The discussion in this chapter highlights some key issues around ES design and technological changes potentially affecting ES. We now look at a brief summary of three key issues from our discussion and suggest directions for further research and suggest what the next generation of ES may deliver in organizations given the developments in technologies discussed in this chapter.

The ES literature has been obsessed with implementation issues because, as discussed earlier in this chapter, implementing such complex and expensive systems does put organizations at severe risk. Hence, the attention in research has been justified. Implementation studies have contributed to our extensive knowledge of the complexity and difficult in the design and deployment of such systems. The fundamental issue stems from the nature of business processes in modern day organizations. IS and most business practices continue to draw on principles drawn from industrial practices in the manufacturing sector. However, nature of work in organizations has shifted from manufacturing-based practices to "services sector"—based practices. Most modern global economies have a large share of their gross domestic product contributed by the services sector. However, this shift in the nature of any economy is not adequately reflected in our systems designs and research activities. Along with the shift to services economy, developments in IT have changed the nature of knowledge creation and its consumption, necessitating a rethink in systems design (Chesbrough and Spohrer, 2006). This is far removed from the dominant manufacturing sector-based economies of the past, where several of our current organizational systems designs were modeled. Hence, ES studies need to reexamine the needs of modern enterprises to design and develop systems that reduce complexity, devolve skills, and decision making to knowledge workers, who can act as process owners.

Much research is needed to understand true knowledge intensive activities in organizational settings and the role information technologies can play in facilitating task performance. In knowledge intensive activities, knowledge creation and application can be devolved to task owners rather than centralizing tasks through complex enterprise applications. In other words, modern ESs have preferred to centralize control and limit access and visibility to its users (Devadoss and Pan, 2007). However, most modern work environments may require the opposite, with devolved control and greater visibility for users of their own tasks and others'. Such systems will then be able to provide the focus on knowledge workers and productivity, as necessary in a modern knowledge economy (Drucker, 1999).

Advances in information technologies should assist in creating simple and uncluttered business processes that can interact with other business processes. This should decentralize business process ownership to assist knowledge users in delivering higher productivity through effective IS, while providing fully functional ability to audit a knowledge workers performance. This implies oversight on tasks and performance for managerial purposes, but decentralization of control and knowledge application to individual users. Simplified user interfaces, consumer friendly devices and greater control over task performance are key issues that will contribute significantly to the growth of ES adoption and its use in organizations. For example, these issues in the context of knowledge management have shown great promise for organizations (Massa and Testa, 2009). In the context of modern and mobile technologies

and growing numbers of enterprise application stores, more research is needed to identify the nature of task performance and the role of IT in assisting knowledge workers. Furthermore, given the growth in mobile applications stores for enterprises, further investigation is necessary to understand their design, development, delivery, and application in organizational use (Giessmann et al., 2012).

Computing ideas from the past have explored environments where users had greater control over design and use of objects in organizations, such as Lotus Notes. End-user computing may have a different context in organizations in modern days, with better-equipped workforce that has greater computer self-efficacy, and also has the need for greater control and flexibility over task performance (Fischer et al., 2004). Furthermore, open source software solutions and associated contributors were expected to revolutionize computing solutions. However, large projects with independent developers, each with varying independent visions for their products have been significant barriers in organizational adoption (Nagy et al., 2010). Though they have made vital contributions in some segments such as Internet applications, open source ES solutions have been difficult due to the design issues in business processes (as discussed in this chapter) and architectures used in such solutions. There is a market for open source ES, though advanced functionality does not come free. As discussed previously, modern day computing solutions are now capable of breaking down solution complexity and facilitating implementation of less complex solutions that focus on specific business process level details. The cost of developing and deploying such solutions are less in terms of time, cost, and risk. This is an emerging area of interest that needs more attention in future, and will have a significant impact on ES applications in organizations given the growing numbers of enterprise application stores (Giessmann et al., 2012). The emergence of mobile platforms and enterprise application stores should also encourage greater development from distributed programming resources and leave design and implementation to process experts instead of technology experts, as suggested by Fischer et al. (2004). The next generation of ES should cater to a new kind of knowledge worker who is equipped with appropriate ES to deploy their expertise to execute their tasks.

25.1 Introduction

Since the inceptions of information technology (IT) and information systems (IS), companies have experienced a constant increase in size, scope, and complexity of enterprise IS. To manage and organize these systems, logical constructions and representations in the form of models were needed, and an architecture approach to IS was developed in response to these challenges. Architectures are used commonly in IT and IS domains to construct blueprints of an enterprise for organizing system components, interfaces, processes, and business capabilities, among others. Architectures are discussed extensively, describing various aspects of IS. Architectures in the wider context of IS are often used to model aspects of a system, especially computer, network, software, application, service-oriented, business, and project-development architectures, among others. Thus, the term architecture plays a central role in IS and IT and can be defined generally as "*the fundamental organization of a system embodied in its components, their relationships to each other, and to the environment, and the principles guiding its design and evolution*" (IEEE Computer Society, 2007).

Combined with increased importance of IS in the 1990s (Morton 1991), information system architectures—and later enterprise architectures (EA)—became important. Yet, this is still a broad and multifaceted domain with various viewpoints. Over the years, many EA frameworks, modeling concepts, and tools were proposed, including the Zachman framework (Zachman 1987), Department of Defense Architecture Framework (Chief Information Officer U.S. Department of Defense 2010), Federal Enterprise Architecture Framework (Office of Management and Budget 2012), The Open Group Architecture Framework (TOGAF) (The Open Group 2011), and Architecture of Integrated

Information Systems (ARIS) (Scheer 1992). The purpose of this chapter is to describe EA from a business and IS viewpoint as well as review prominent EA frameworks. A common concept found among all frameworks is the conceptualization of strategic business decisions in systems design choices, in which EA aims to support and enable transformations within an organization while aligning business and IT. To reduce complexity, many frameworks use views to describe elements of architectural content (e.g., strategy, information, process, service, and technology). Each view is meaningful to various stakeholder groups. The intent of EA is to determine—from various stakeholder viewpoints—how an organization can most effectively achieve current and future objectives in the form of transformations. Strategic options are often translated into systems design options, and EA helps manage this process carefully.

The terms enterprise architecture (EA) and enterprise architecture management (EAM) are often used interchangeably (Ahlemann et al. 2012b), though the scopes of the two are different. EA is concerned with creation in the form of design and development of architectural blueprints and artifacts; EAM is concerned with the sustained management of such artifacts using lifecycles. Consequently, EAM is a process to plan, control, govern, and evolve an enterprise's organizational structure, business processes/services, and technical infrastructure in accord with a vision and strategy. We view EAM as part of EA, and hence, refer only to the EA discipline as whole. EA is concerned with business process integration and standardization (Ross et al. 2006), and thus, business processes are at the core of EA. We view EA from a business process and modeling perspective, though EA often includes a large variety of IS-related viewpoints and approaches in practice.

25.2 Positioning Enterprise Architecture

EA evolved into its own research domain, and various ways of positioning and organizing EA emerged (Ahlemann et al. 2012b; Dern 2009; Hanschke 2010; Op 't Land et al. 2009; Ross et al. 2006; Scheer et al. 2000; Schmidt et al. 2011; The Open Group 2011). Early work on architectures model aspects of systems, often referred to as IS or system architectures. These architectures do not emphasize strategic directions or business aspects strongly (Kim et al. 1994). Given a need for IT and business alignment and coming from early system-oriented concepts, a widely adopted approach emerged that organizes EA along various organizational layers and emphasizes an IT business alignment paradigm. The purpose is to relate strategic aspects to application and technology. Layering helps researchers and managers understand and describe the scope and function of EA as they relate to boundary points from business strategy to technical infrastructure. Figure 25.1 illustrates both architectural layers and the contexts with which they interact. Usually, strategic planning serves as input for EA, especially when EA is viewed as a strategy-driven enterprise function. Core layers represent business architectures (BAs), application architectures (AAs) (including data/information architectures), and technology architecture, all used with EA processes and services to design, develop, govern, and manage them. EA produces some form of content or output such as artifacts (Winter et al. 2006) and principles (Greefhorst et al. 2011). In addition, EA uses frameworks and tools.

We view EA from a service perspective; each layer offers a service to the business, and the service-oriented paradigm occurs in each architectural layer. For example, the technology architecture offers infrastructure services in the form of hardware and networks. The application architecture provides services centered on software applications and data. The BA is concerned with business processes and services. The BA, through business processes, emphasizes the dynamic aspects of workflows and activities supported by application components and infrastructures. Examples in the literature present simple, three-layered frameworks with which to view EA (Hasselbring 2000; The Open Group 2012) to multilayered EA frameworks (Winter et al. 2006). Approaches that include enterprise strategy as a separate layer are also documented (Godinez et al. 2010). Whether or not strategy is a dedicated EA layer,

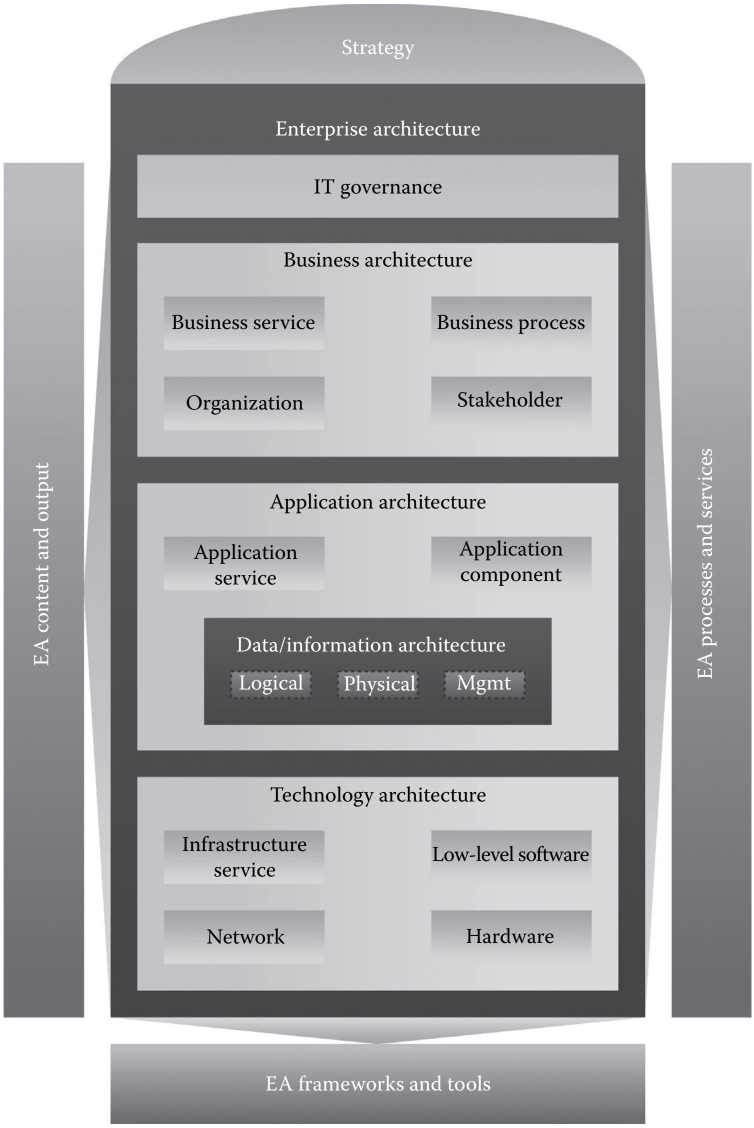

FIGURE 25.1 EA overview.

it initiates a discussion of whether EA is solely an IT or also a business function. Due to the strategic importance of business–IT alignment (BITA), we argue EA is a hybrid enterprise function (Ahlemann et al. 2012b). In the following sections, we describe EA processes and services, the role of IT governance, and core architectural layers.

25.2.1 EA Processes and Services

EA services provide benefits to stakeholders within an organization and may consist of several EA processes. EA service model (Robertson 2008) can be introduced to document the service delivery of EA. An example is described in Table 25.1. Notably, there are more processes in relation to these fundamental EA services, and EA services need to be adapted to specific enterprise contexts.

TABLE 25.1 Example EA Service Model

EA Services	Design	Development	Management	Training and Support
EA processes	• Define standards • Define guidelines • Define principles	• Build • Implement	• Governance • Planning	• Consulting • Training • Support
Roles	• Business architect	• Enterprise architect	• Business architect • Enterprise architect	• All
Outcomes (deliverables)	• Standards • Guidelines • Principles	• Strategic architecture • Solution architecture • Artifacts	• Reports	• Training material
Benefits	• Standardization	• Reduced complexity • Improved integration	• Improved decision support • Improved risk management • Reduced costs	• Common understanding • Improved skills • Improved knowledge

25.2.2 Role of IT Governance

In the context of EA, the role of IT governance is important since it provides a means for management to direct and govern IT toward desired outcomes (IT Governance Institute). IT governance is a tool that provides necessary means to achieve strategies and goals. EA is crucial for effective IT governance because it provides methods to measure success (Weill et al. 2004). However, a holistic model that describes IT governance in an enterprise context has not surfaced due to the complexities and diversity of perspectives inherent in the domain (Rüter et al. 2006). EA governance is a subdiscipline of IT governance that focuses on the principles, decision rights, rules, and methods that drive architecture development and alignment in an organization (Greefhorst et al. 2011). EA governance is concerned with standardization and compliance with current and future practices.

25.2.3 Business Architecture

BA, the top layer of EA, typically contains business processes/services, organizational structures (including roles and responsibilities), and value drivers, which are aligned to a strategy divided into goals and objectives (The Open Group 2011; Versteeg et al. 2006). BA marks the foundation of effective BITA, and sample scenarios in a BA context include (The Open Group 2010) the following:

- Mergers and acquisitions planning and developments
- Business unit consolidations
- New product and service rollouts
- Introduction of new lines of business
- Consolidating suppliers across supply chains
- Outsourcing business functions
- Divesting business lines
- Management changes
- Regulatory compliances
- Operation cost reductions
- Federated architecture alignments in government
- Business transformations
- Entering international markets

25.2.4 Application Architecture

AAs deal with combined logical capabilities, developing specifications for individual applications including interactions and relationships to business processes. Applications offer services to other business units. Within AA, service-oriented architectures (SOA) (Erl 2007; Krafzig et al. 2007) and cloud computing (Mahmood 2011) are discussed often. These emerged as recent EA paradigms, besides classical enterprise application integration challenges.

25.2.5 Data/Information Architecture

We argue data and information architectures (DA/IA) are situated as part of the AA layer, due to its importance and relation to applications. This does not mean this sub-layer is unimportant or can be seen in isolation; in fact, many view it as the core of an enterprise relating to multiple layers of EA, referred to as the data-centric view. Information consists of business objects such as orders and production plans, and includes raw information gathered throughout the company by means of performance measures (Neely 2004) and translating it into meaningful information as a key objective of EA (Godinez et al. 2010). In this way, DA/IA relates to business processes and translates information into a business context. Consequently, it is an important EA aspect because it has significant impacts on the business, and quality of data and information is particularly important (Borek et al. 2012). It comprises the logical, physical, and management views that provide sufficient information to form a basis for communication, analysis, and decision-making (Allen et al. 1991; Xie et al. 2011). For example, EA is concerned with data models, logical and physical models, data flows and transformations, metadata, and standards on how information should be stored and exchanged.

25.2.6 Technology Architecture

The technical layer of EA is concerned with an underlying infrastructure (i.e., hardware and system-level software). Hardware includes servers and network infrastructures, and all of their components. Applications are built using appropriate infrastructures, and hence, this layer provides required infrastructure services. An example service at this layer is the provisioning of a server. Technology architecture offers infrastructure services to applications; notably a database is a type of infrastructure.

25.3 Reasons for Enterprise Architecture

To provide a review of reasons to employ EA, we examine various EA drivers and key EA applications, and we describe benefits and common outputs of EA.

25.3.1 EA Drivers

EA drivers are the primary reasons for enterprises to employ EA, and one of the most important drivers is BITA (Schöenherr 2008). Critical aspects are described in detail when aligning business and IT (Henderson et al. 1993; Luftman 2003; Mahr 2010; Pereira and Sousa 2005). Cost reductions and managing complexities are other important EA drivers. For example, dismantling legacy systems and components reduces costs, and EA reduces complexity by providing a streamlined and manageable system landscape described through various models. In addition to these important and frequently mentioned drivers, some external drivers do not originate within the enterprise. An example is regulatory compliance requirements issued by legal organizations or governments to which the enterprise must adhere.

TABLE 25.2 Benefits of EA

Technology-related benefits	
IT costs	When reducing non-value-added variations of technologies, a company can reduce IT operations unit and application maintenance costs.
IT responsiveness	Through standardization, decision-makers spend less time choosing the right technologies or dealing with recurring errors; thus, development time is reduced, increasing overall IT responsiveness.
Risk management	IT infrastructure cleanup improves manageability, and thus, contributes to reduced business risk, improved regulatory compliance, increased disaster tolerance, and reduced security breaches.
Business-related benefits	
Shared business platforms	Through data and process standardization, greater data sharing and integrated process standards emerge.
Managerial satisfaction	Although subjective, satisfaction indicates the confidence of business executives in the ability of IT to deliver business value; an increase in senior management satisfaction and business unit IT leadership results from effective EA.
Strategic business impacts	EA enables: • Operational excellence • Customer intimacy • Product leadership • Strategic agility

25.3.2 EA Benefits and Value Contributions

Outcomes and benefits depend on context and the extent to which an enterprise uses EA. Usual EA output is described in the form of principles, models, and architecture views. Less tangible outputs in the form of common understanding and improved communications are benefits of EA. In the literature, a number of researchers discuss EA contributions in terms of direct benefits and business value (Ahlemann et al. 2012b; Meyer et al. 2012; Ross et al. 2006; van Steenbergen et al. 2011). We summarize some of the typical EA benefits in Table 25.2 (Ross et al. 2005).

25.4 EA Frameworks

A number of EA frameworks emerged over the past few decades (Schekkerman 2006), and several studies of evaluations and analyses of select EA frameworks exist, based usually on varying foci (Leist and Zellner 2006; Tang et al. 2004). To provide an overview of typical frameworks, we describe well-known and widely used ones in the following section. Common to these frameworks is reducing enterprise complexities by considering disparate viewpoints and organizing various aspects in ways that make an enterprise understandable. Another important purpose is support for an architecture development process. The EA process provides directions and guidelines to architects to design a model or even an entire architecture.

25.4.1 Zachman EA Framework

Seminal work on the Zachman framework (Zachman 1987) was a key contribution to EA. As IT became more complex, a need arose for a method to organize complex IS. For this reason, primitive

interrogatives of *what*, *how*, *when*, *who*, *where*, and *why* identify aspects of an enterprise. The reification or transformation of an abstract idea into an instantiation is labeled *Identification*, *Definition*, *Representation*, *Specification*, *Configuration*, and *Instantiation*. Intersections among the interrogatives and transformations result in 6 by 5 matrix. Another important aspect of this framework is consideration of roles (i.e., stakeholders) related to the various perspectives.

The Zachman framework provides a schema for describing the structure of an enterprise; it represents ontology since it provides a structured set of an object's essential components. It is a meta-model, without implying how to establish architecture. In its current version 3.0, the Zachman framework is an 8 by 8 matrix, depicted in Figure 25.2. It is important to note that this framework was not conceived originally as a methodology since it did not provide a process to instantiate an object (i.e., implement the enterprise). The limited focus on the meta-model design may not warrant consistency among layers and views. Nevertheless, there exist some methodological approaches for applying this framework (e.g., Marques Pereira et al. 2004).

25.4.2 Generalized Enterprise Reference Architecture and Methodology

To provide a conceptual basis for IS architectures, the Generalized Enterprise Reference Architecture and Methodology (GERAM) framework was developed by the IFAC/IFIP (IFIP IFAC Task Force on Architectures for Enterprise Integration 2003), building on (Bernus et al. 1996, 1997). One advantage of using GERAM is that it is not a domain-specific architecture; it is a general framework of concepts for designing and maintaining any type of enterprise. GERAM is a framework in which all methods, models, and tools necessary to build and maintain an integrated enterprise are defined; however, it is limited in providing guidelines or reference models for EA in practice. The framework applies to all types of enterprises, including part of an organization, a single organization, or a network of organizations.

Illustrated in Figure 25.3, GERAM is based on the lifecycle concept and identifies three dimensions for defining the scope and content of enterprise modeling:

- *Lifecycle dimensions*, which provide for a controlled modeling process of enterprise entities according to lifecycle activities
- *Genericity dimensions*, which provide for a controlled instantiation process from generic and partial to particular
- *View dimensions*, which provide for a controlled visualization of views of the enterprise entity

To facilitate efficient modeling by enhancing the modeling process, GERAM uses one important concept; it provides various partial enterprise models with an underlying generic enterprise modeling concept. Instead of developing new models within the process, models and concepts are adopted and configured for each situation. Since these concepts and models play an important role in integrating heterogeneous systems, we focus on partial enterprise models (i.e., reference models), including their supported generic modeling concepts. Partial enterprise models are reusable models of human roles, processes, and technologies that capture characteristics common to many enterprises within and across one or more industries. They include various enterprise entities such as products, projects, and companies and may represent each from various viewpoints. To describe multiple levels of abstraction along lifecycle phases, partial models exist at various levels, including concept, requirements, and design levels. Generic enterprise modeling concepts define enterprise modeling constructs. These concepts may be defined using natural language (e.g., glossaries), meta-models (e.g., entity relationship meta-schema), or ontological theories. Bernus et al. (2010) took the GERAM meta-model to the next level by incorporating standards such as IEEE Computer Society (2007) and ISO/IEC (2000), though one of the older frameworks never found a place in practice because of its overwhelming complexity.

Audience perspectives / Classification names	What	How	Where	Who	When	Why	Classification names / Model names
Executive perspective (business context planners)	Inventory identification	Process identification	Distribution identification	Responsibility identification	Timing identification	Motivation identification	Scope contexts (scope identification lists)
Business Mgmt perspective (business concept owners)	Inventory definition	Process definition	Distribution definition	Responsibility definition	Timing definition	Motivation definition	Business concepts (business definition models)
Architect perspective (business logic designers)	Inventory representation	Process representation	Distribution representation	Responsibility representation	Timing representation	Motivation representation	System logic (system representation models)
Engineer perspective (business physics builders)	Inventory specification	Process specification	Distribution specification	Responsibility specification	Timing specification	Motivation specification	Technology physics (technology specification models)
Technician perspective (business component implementers)	Inventory configuration	Process configuration	Distribution configuration	Responsibility configuration	Timing configuration	Motivation configuration	Tool components (tool configuration models)
Enterprise perspective (users)	Inventory instantiation	Process instantiation	Distribution instantiation	Responsibility instantiation	Timing instantiation	Motivation instantiation	Operation instances (implementation)
Audience perspectives / Enterprise names	Inventory sets	Process flows	Distribution networks	Responsibility assignments	Timing cycles	Motivation intentions	Enterprise names / Model names

FIGURE 25.2 Zachman framework version 3.0.

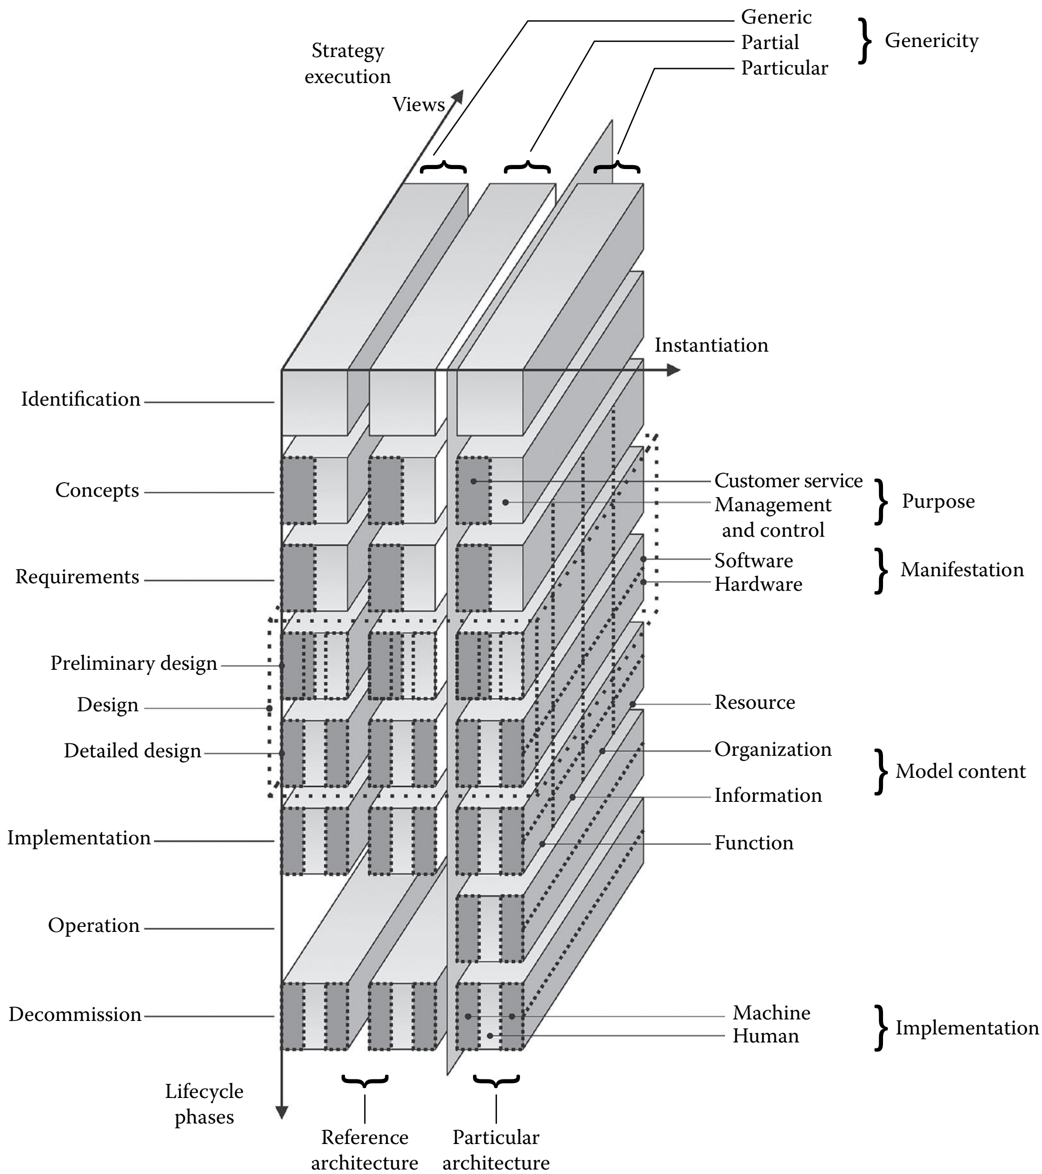

FIGURE 25.3 GERAM cube.

25.4.3 ARIS

The ARIS framework is a prominent architectural framework often used in practice that represents various aspects of information system design (Scheer 1992). The framework has its roots in the 1980s, with a trend toward corporate data models and material requirements planning. The ARIS house (Figure 25.4) is an architecture that describes business processes, providing modeling methods and meta-structures combined with suggestions for modeling techniques. As a modeling technique and methodology, ARIS is a model for comprehensive, computer-aided business process management, although only representing selected EA views and layers. The concept is also incorporated in a toolset

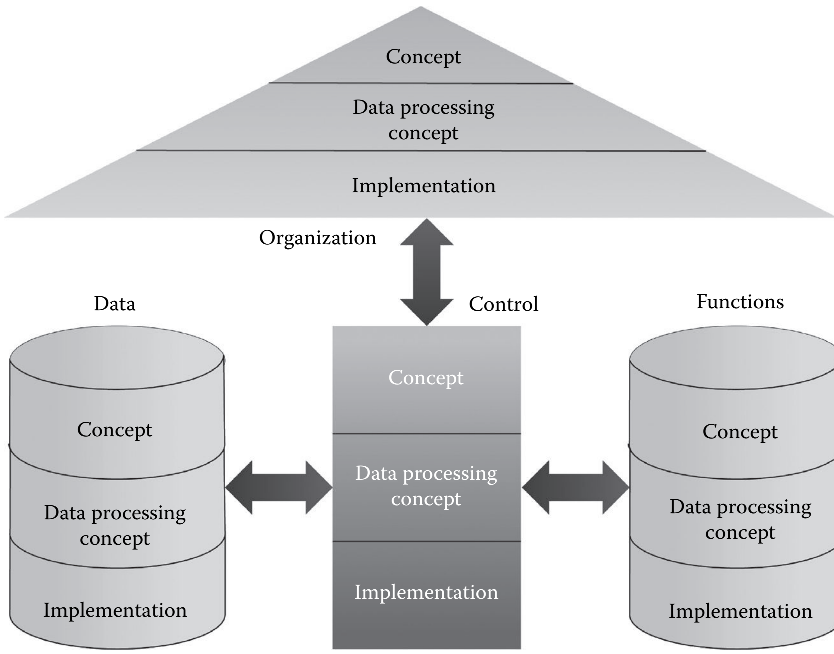

FIGURE 25.4 ARIS house.

to support modeling. To reduce complexity, the model is divided into individual views that represent discrete design aspects:

- *Data view*: Conditions and events form the data view. Events such as order, order reception, and production release are information objects represented by data. Reference field conditions such as customer status and article status are also represented by data
- *Function view*: Functions to be performed and relationships among them
- *Organization view*: Structure and relationships among staff members and organizational units
- *Control view*: An essential component that restores and retains relationships among the various views. By structuring a process, it incorporates a data, function, and organizational view

25.4.4 TOGAF

TOGAF (The Open Group 2011) is a comprehensive methodology, including a set of tools to develop an EA. It is based on an iterative process model supported by best practices and a reusable set of existing architecture assets. TOGAF offers clear definitions for various terms, including basics such as architecture(s), views, and stakeholders. TOGAF is organized into three primary sections: *Architecture Development Method* (ADM), *Enterprise Continuum*, and *Architecture Repository*. Additionally, TOGAF provides a comprehensive content meta-model that describes entities and their relationships to ensure common understanding of framework mechanics.

The ADM is a generic method used to realize an organization-specific EA in accord with business requirements. It is organized into several phases, each of which contains various steps to achieve the desired output at the current stage of development. Combined, all phases mark the complete development lifecycle. The *Enterprise Continuum* represents a view of the repository containing all architecture assets, including architecture descriptions, models, building blocks, patterns, and viewpoints, in addition to other architecture and solution artifacts. Architecture and solution artifacts can be internal or external. Internal artifacts are extant architecture assets such as models that are ready for reuse. External artifacts

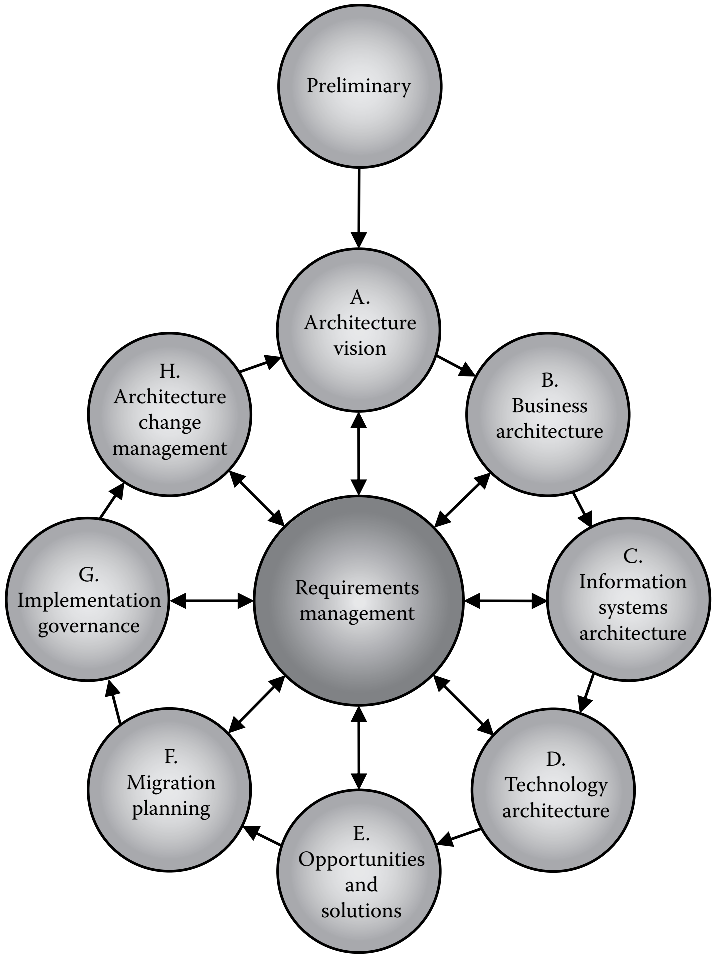

FIGURE 25.5 TOGAF architecture development method (ADM).

comprise industry reference models and architecture patterns that are applicable to aspects of IT and industry and are constantly emerging and evolving. The *Architecture Repository* supports the Enterprise Continuum by storing classes of architectural output at varying levels of abstraction. The ADM generates this output during several phases. The ADM and its phases are depicted in Figure 25.5.

25.4.5 Other Frameworks

While there exist a number of dedicated EA frameworks (Schekkerman 2006), there are also some related IT frameworks, occasionally working with them, such as IT Infrastructure Library (ITIL) (Office of Government Commerce 2007) and Control Objectives for Information and Related Technology (COBIT) (IT Governance Institute 2007). ITIL is the standard for IT service management. Control objectives for Information and Related Technology (COBIT) began as an IT governance framework, but it has evolved since to a comprehensive IT framework comprised of control objectives, reference processes, management guidelines, and maturity models. Both frameworks mention EA explicitly and demonstrate how they consider EA's position. COBIT considers EA an explicit IT function, concerned with IT processes with goals derived from business goals as input. ITIL follows a more traditional domain or layer approach, introducing domains such as service, environmental, management, and product architectures.

25.5 EA Modeling

EA modeling is an essential part of contemporary EA practice. Since the EA discipline is concerned with developing a blueprint for an enterprise, practitioners use a variety of models such as data, business interaction, and organizational models (Olivé 2007). An example of an EA modeling language is ArchiMate (The Open Group 2012), based loosely on Unified Modeling Language (UML). ArchiMate supports three layers for modeling—business, application, and technology—each of which contains various modeling elements. The language aligns fully with TOGAF, and each layer connects to ADM phases. Looking at the content meta-model of ArchiMate (The Open Group 2012), each layer offers services. The technology layer offers infrastructure services to the application layer, which in turn offers application services to the business layer. The latter provides the actual business service, consumed either within the enterprise or by external clients. We reflect the SOA paradigm in this language.

Chen et al. (2009) present a domain-modeling approach based on the Zachman framework. UML is one of the most important languages in enterprise modeling. With its great diversity of diagrams, it offers views and models for many situations both at a high level of abstraction when it comes to conceptualization and at a low level for comprehensive technical documentation of inner application aspects. Although the primary foci and applications of UML are software architectures, many enterprise architects use UML (or some derivative) to accomplish the modeling part of their work (i.e., to produce EA artifacts based on models) (Kruchten et al. 2006).

At the center of BAs are business processes, which capture dynamic aspects of the business element in an enterprise. Regarding modeling, there are many process and workflow modeling languages such as Business Process Modeling Notation (Business Process Management Initiative 2011), Event Driven Process Chains (Scheer 1999), Business Process Execution Language (OASIS 2007), and others (List and Korherr 2006). Business Process Management System is a generic software system driven by explicit process designs to enact and manage operational business processes (Weske 2007). It offers a platform that allows both modeling and execution, and is an important part of enterprise modeling and, hence, EA (Grunninger 2003; Scheer et al. 2000). Regardless of models or modeling languages, it is critical that stakeholders understand them (Kaisler et al. 2005).

25.6 Practical Aspects of EA

In larger enterprises, a team of enterprise architects usually conducts the EA function (Murer et al. 2011). In smaller companies, EA is often part of the IT department, with no separate EA unit. Most companies use some of the common EA frameworks even though they are, in many cases, adapted or customized. However, employing a framework alone does not provide an EA; architects are a necessary component. Depending on the company, there are a few architecture job descriptions with varying skill sets such as solution, data, and enterprise architects. We must be concise about who participates in the EA function and what their function is. The Open Group (2011) details a presentation of EA roles and associated skills, and Ahlemann et al. (2012a) outline another explanation of what types of architects are needed. Another practical aspect is EA maturity, indicating how much the function has evolved in terms of various aspects such as architecture planning, value, and stakeholder communication. All EA processes should be supported by a variety of EA tools, and we examine that support in terms of EA processes and services.

25.6.1 EA Maturity

Maturity is a measure that describes advancement and progress in business processes or EA. At each stage, maturity indicates whether requirements are met. Ross (2003) outlines a general description of EA maturity and its stages. The four stages are characterized by management practices to design and protect the architecture. In the first stage, we find business silos, and within them, business cases and project methodologies. In stage two, standardized technologies and structures are in place, including

an IT steering committee, a formal compliance process, centralized handling of enterprise applications, and architects on a project team, among other practices. An optimized core marks the third stage where process owners, EA principles, business leadership of project teams, and IT program managers are in place. The last maturity stage is called business modularity, characterized by an EA graphic, post-implementation assessments, technology research, adoption processes, and a full-time EA team.

There exists a variety of EA maturity frameworks, and Meyer et al. (2011) present an overview and analysis. All of these frameworks possess classifications and characteristics of an EA and a method to assess it. The IT Capability Maturity Framework (IT-CMF) (Curley 2006, 2009) offers five maturity levels for nine capability building blocks. It comprises aspects of planning, practices in the form of governance, processes and value contributions, and organizational and communication aspects. IT-CMF offers detailed assessment for each capability building block.

25.6.2 EA Tools

Companies have broad choices when using EA tools, and these tools help enterprise architects and other stakeholders plan, model, develop, and monitor architectures. As with most business software, companies are not always dependent on vendor solutions, and may choose to develop their own. Most EA tools offer

- EA planning
- EA modeling
- EA simulation and improvement
- EA monitoring and reporting
- Shared artifact repository
- Reusability support

An overview of EA tools and a selection guide is available online from the Institute For Enterprise Architecture Developments (2012), and Wilson and Short (2011) provides a magic quadrant for EA tools.

25.7 Critical Aspects

EA should reduce structural and operational complexity within an organization. Conducted properly, EA delivers projected benefits as discussed earlier, but it can be an investment without any significant return. One challenge with EA is that it is not always obvious what enterprise architects do, how architects generate business value, and whether investments in EA are necessary (Meyer et al. 2012; Robertson 2008). A first step is to generate an EA service model. Mentioned earlier, EA has come a long way over the past few decades, but there is still no single definition or unifying framework. GERAM provides a useful meta-framework, however, with less practical applicability. The Zachman framework and ARIS offers great flexibility and is often used in practice, but is limited with its meta-model and methodology. TOGAF together with ArchiMate supports modeling in conjunction with an ADM but can be challenging to adapt in a practical setting. In practice, often a combination of several frameworks can be found. Also, several studies of evaluations and analyses of select EA frameworks exist (e.g., Leist and Zellner 2006; Tang et al. 2004). Furthermore, distinctions among processes such as EA development and EA management do not appear in the literature. Although Schöenherr (2008) points out that common terminology is important for the EA discipline, we are unable to offer concise descriptions of what EA is and does, and Kaisler et al. (2005) mention critical problems with EA that are barely solved after years of research.

25.8 Summary

Since its origins, described as IS Architecture in the 1980s and 1990s, EA evolved into an extensive domain with numerous approaches and frameworks. A core characteristic of EA is that it enables and supports constant transformations of an enterprise from a current to a target state. EA supports this

transformation with tools and frameworks to manage complex enterprise systems. We outline prominent frameworks and modeling approaches and describe the importance of practical tools. EA provides directions and guidelines for high-level enterprise evolvement by encapsulating and relating business aspects, application portfolios, information and data, and technology. Related to strategic management, alignment of business and IT is one of the most important drivers of EA. An effective EA function yields a number of benefits such as reduced complexity, reduced risks, reduced costs, and improved business–IT alignment (Lankhorst 2009; Op 't Land et al. 2009; Ross et al. 2005, 2006; van Steenbergen et al. 2011). Enterprises evolve constantly; producing drivers for employing an EA function—with all its capabilities—make it an ever-emerging discipline. New developments and innovative modeling approaches, tools, and model-based EA frameworks can be expected, combined with practical methods to employ and value EA in enterprises. These are the foci of current research and development.

Business Process Management and Business Process Analysis

Jan vom Brocke
University of Liechtenstein

Christian Sonnenberg
University of Liechtenstein

26.1 Introduction

"Panta rhei"—"everything flows"—an aphorism leading back to the thoughts of Heraclitus provides a metaphor for the *dynamic nature of physical existence*. Humans have been conceiving sets of actions ever since to deal with and survive in a dynamic environment. Sets of consecutive actions that are directed to some end are commonly referred to as a *process*. In fact, human societies are organized around such generic processes as crafting tools, producing energy, producing food, producing goods, building structures, making astronomical observations, communicating messages, or celebrating rituals. Process can also be perceived on the level of an individual like preparing a meal, buying a car, or simply completing a to-do list. For processes that require the participation of multiple individuals and that are intended to be executed on a continuing basis are usually embedded within an *organization*.

Consequently, an organization can be best described in terms of *what it does and can do* (cf. Rescher, 1996) and processes—in a very simple sense—are *what companies do* (cf. vom Brocke and Rosemann, 2013). The capability and potential performance of an organization is thus built into its processes. Processes do happen, regardless whether we manage them or not. Managing processes, therefore, intends to make sure that the organization meets the requirements in operating processes that support the strategic corporate objectives. Over the past decades, business process management (BPM) emerged

as an academic discipline that intersects with both information systems and management research. BPM represents an integrated, process-oriented management approach utilizing tools and methods for business process analysis and improvement (cf. Rosemann and vom Brocke, 2010).

The BPM discipline, as it is understood today, evolved around two main strands (Hammer, 2010):

- *Continuous change*: Earlier studies focused on continuous or incremental improvement of existing processes. Examples of this approach have been total quality management (TQM), lean management, or kaizen. Basic methodological principles have been contributed by Deming, for example, on statistical process control, dealing with a systematic analysis of processes by means of both quantitative and qualitative criteria (Deming, 1986).
- *Radical change*: By introducing the concept of business process reengineering, Hammer and Champy (1993) advocated an approach, which is based on the fundamental rational to challenge all existing processes in an organization. Here, the goal is to rethink and, if deemed appropriate, redesign business processes from scratch (so-called green field approach). Information and communication technology is considered to be the main facilitator and driver of such radical process redesigns (Davenport, 1993). The focus is less on fine grained analytical methods but more on discussing the design of "large-scale, truly end-to-end processes" (Hammer, 2010, p. 4).

Today, BPM aims to combine both approaches (Hammer, 2010), recommending that there should be an alternation of activities of continuous improvement and radical change (vom Brocke and Rosemann, 2013).

26.2 Core Elements of BPM

In order to enable the management of processes in an effective and efficient way, companies need to develop a wide range of capabilities. From research on maturity models (de Bruin et al., 2005), six central core elements for BPM were derived (Rosemann and vom Brocke, 2010). They are shown in Table 26.1 and are briefly explained in the following.

- *Strategy*: Process management needs to be guided by strategic organizational goals. The main question to answer: How can each process be assessed in order to be able to determine its specific value?
- *Governance*: Process management needs to be rooted in the organizational structure. The main question to answer: Who is supposed to be responsible for which process management task?
- *Methods*: Process management needs methods for process design supporting different phases of process development. The main question to answer: What methods are being used by the organization?
- *Technology*: Process management needs to be supported by technology, particularly information technology (IT), as the basis for process design. The main question to answer: What systems are available in the organization in order to be able to execute different process management tasks?
- *People*: Process management needs certain capabilities and skills on the part of an organization's staff. The main question to answer: What capabilities and skills are available and what must be done to develop missing capabilities?
- *Culture*: Process management needs a common value system in order to effect certain changes required. The main question to answer: Is the culture of an organization and the basic attitude of its people supportive of change and innovation?

Research on BPM has shown that no core element should be neglected when BPM is to be implemented successfully in an organization (e.g., Bandara et al., 2007; Kettinger and Grover, 1995; Trkman, 2010). The challenge is to develop each core element adequately while at the same time matching all core elements with each other in a reasonable way. The context an organization is embedded in plays a crucial role here. There is no "out-of-the BPM approach" that can be readily applied to any organization whatsoever.

TABLE 26.1 Core Elements of BPM

Business Process Management

Core Elements

Strategic Alignment	Governance	Methods	Information Technology	People	Culture
Sub-Elements					
• Process improvement plan • Strategy and process capability linkage • Process architecture • Process output measurement • Process customers and stakeholders	• Process management decision making • Process roles and responsibilities • Process metrics and performance linkage • Process management standards • Process management controls	• Process design and modeling • Process implementation and execution • Process control and measurement • Process improvement and innovation • Process project and program management	• Process design and modeling • Process implementation and execution • Process control and measurement • Process improvement and innovation • Process project and program management	• Process skills and expertise • Process management knowledge • Process education and learning • Process collaboration and communication • Process management leaders	• Responsiveness to process change • Process values and beliefs • Process attitudes and behaviors • Leadership attention to process • Process management social networks

Source: Rosemann, M. and vom Brocke, J., The six core elements of business process management, In: *Handbook on Business Process Management*, Vol. 1, ed. vom Brocke, J. and Rosemann, M., Springer, Berlin, Germany, pp. 107–122, 2010.

Every organization has to analyze and decide very precisely what their particular BPM approach with regard to each of the six core elements should look like.

The particular BPM approach taken is dependent not only on the actual maturity level attained within the six core elements but also on the organization-specific perception of the business process concept. There are several views about the nature of business processes that require BPM activities to be approached differently depending on the view adopted. The subsequent section briefly sketches four possible views on business processes and outlines how BPM activities—in particular process analysis tasks—can be organized within a BPM life cycle. It will also be discussed how different views both enable and limit specific approaches to business process analysis.

26.3 On the Nature of Business Processes and Process Analysis

26.3.1 Common Business Process Definitions

A typical definition of a business process as presented in a large number of BPM literature regards business processes as a *sequence of activities generating a specific value for a customer* (e.g., Davenport, 1993; Hammer and Champy, 1993). The activities contained in a business process are assumed to transform some *input* of suppliers into *outputs* for customers, whereby the transformation activities can be hierarchically decomposed into sub-processes (vom Brocke and Rosemann, 2013). *Activities* in a process are not always arranged in a strict sequence but they are rather linked though network structures.

These network structures determine the order in which entities may flow through a process. The network structure of activities is also frequently referred to as *control flow*, and the entities flowing through a process are referred to as *flow units* (cf. Anupindi et al., 2012). To evaluate process performance, process managers are often interested in analyzing the paths of individual flow units to calculate process performance measures such as *flow time*, *inventory* (total number of flow units present within a process), *quality*, *cost*, or *value-added* (determined in terms of added or changed flow unit attributes that customers consider important). In this regard, some process definitions account for the significance of flow units for distinguishing between processes. For example, Becker and Kahn (2011) define a process as a "timely and logical sequence of activities necessary to handle a business relevant object" (cf. Becker and Kahn, 2011). *Resources* and *information structures* are needed to enable and coordinate the transformation of inputs into outputs. *Resources* (like raw materials, manufacturing facilities, equipment, or employees) are required by individual activities within control flow to process flow units. An appropriate *information structure* supports managerial decision making within a process on an operational and strategic level. In summary, five aspects are central for managing processes (cf. Anupindi et al., 2012):

1. Inputs and outputs
2. Flow units
3. Activities and control flow structures
4. Resources
5. Information structure

Figure 26.1 illustrates how these aspects relate to the concept of a process. Figure 26.2 extends on this conceptualization by illustrating the central characteristics of a business process.

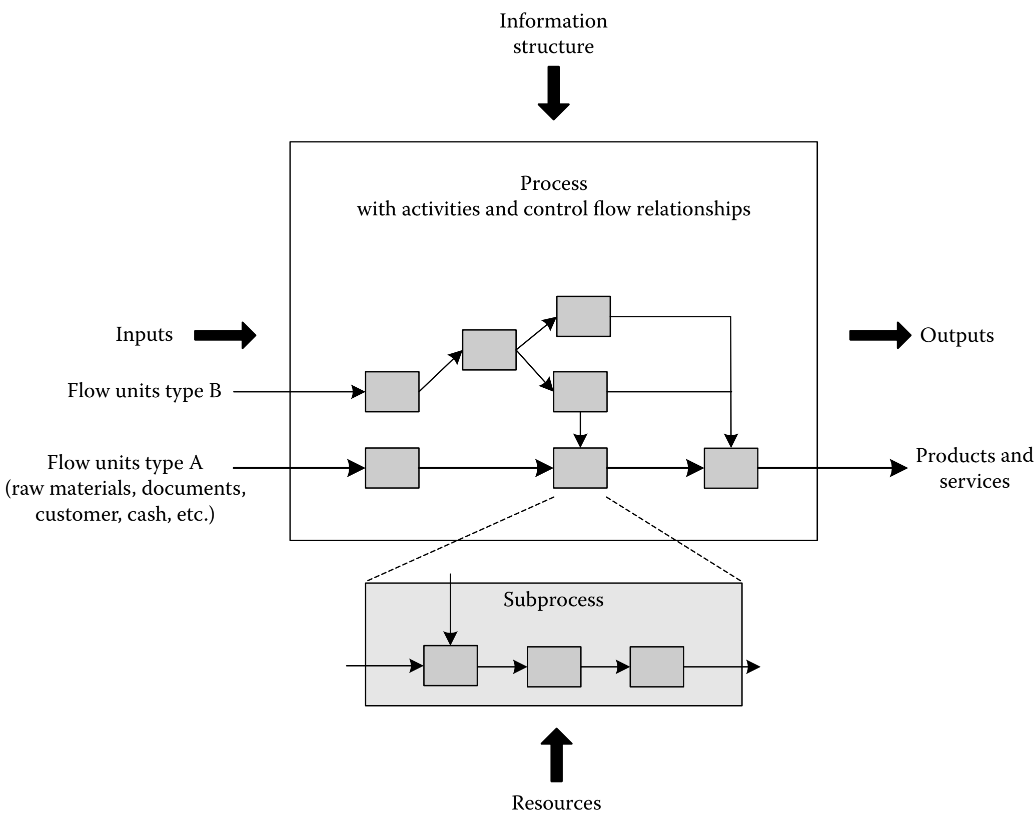

FIGURE 26.1 A process as set of activities linked through control flow relationships.

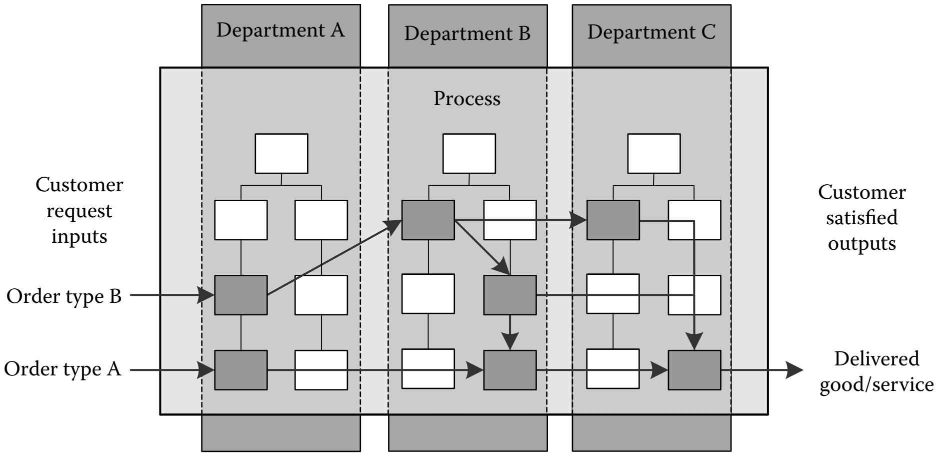

FIGURE 26.2 Business process as cross-functional process.

A business process is commonly regarded as a particular process type which is characterized as having *interfaces to a customer or a supplier* and which contains the activities that represent the *core business* of an organization (cf. Becker and Kahn, 2011). Business processes are thus designed and perceived as *end-to-end processes* (see Figure 26.2). An example of a typical end-to-end business processes is an "Order-to-Cash" process, which comprises all activities for generating and fulfilling a customer order and to collect the payments for fulfilling an order. These activities are usually divided into sub-business processes like "Sales," "Purchasing," "Production," "Shipment," and "Delivery."

Ultimately, the application of BPM in organizations requires a "thinking in processes." Process thinking emphasizes the significance of inter-departmental, cross-functional coordination of business activities with the aim to better serve customer needs (cf. Hammer, 2010). Traditional "functional thinking" on the contrary would rather emphasize the "local optimization" of activities within a particular function by exploiting resource efficiency gains through specialization. However, this local optimization does not necessarily yield an overall optimal coordination of all the cross-functional activities involved in a business process. "Process thinking," as mandated by BPM, stimulates optimization across an organization along defined process structures and to effectively and efficiently coordinate activities in the interest of customer needs.

26.3.2 Views on Business Processes

While the general understanding of the business process concept as outlined earlier is a useful common denominator for BPM, real-world processes are multifaceted and show great diversity according to their specific nature. BPM thus has to account for this diversity by allowing business processes to be approached from different perspectives. Melão and Pidd (2000) present four different views on business processes. According to them, processes can be viewed as (1) a *deterministic machine*, (2) a *complex dynamic system*, (3) an *interacting feedback loop*, or (4) a *social construct*. These views emphasize different important features of a business process and also resemble different assumptions about organizational life (cf. Walsham, 1991). In the following paragraphs, these views are briefly outlined along with their implications on BPM practice and research.

26.3.2.1 Business Process as a Deterministic Machine

According to this view, a process is regarded as a "fixed sequence of well-defined activities or tasks performed by 'human machines' that convert inputs into outputs in order to accomplish clear objectives" (see discussion earlier) (Melão and Pidd, 2000). This view holds that a process can be objectively

perceived and described in rational and technical terms. Process descriptions focus on the *process structure* (routing of flow units), *procedures* (logical dependencies between activities, constraints, and required resources), and *goals*. Goodness of a process is evaluated in terms of *efficiency* measures like time, costs, or productivity. This view has its roots in scientific management (Taylor, 1911) and assumes the presence of stable and structured processes as can be observed in manufacturing processes or bureaucratic processes.

For a long time, this view dominated the BPM practice and research since it is mostly concerned with capturing process knowledge within semi-formal process descriptions and graphical process models (flow charts) of all kinds. This "machine view" assumes that any process type, technical or human driven, structured, and unstructured, can be unambiguously mapped to a process model by means of a dedicated modeling formalism. Exemplary modeling formalisms are discussed further in the subsequent sections and are summarized in Table 26.2. Process modeling under a machine view is applied in a wide variety of domains for various purposes, for example, in software engineering (e.g., the unified modeling language (UML) with its activity and sequence diagrams is heavily used here),

TABLE 26.2 Summary of Different Perspectives on Business Processes

	Deterministic Machine	Complex Dynamic System	Interacting Feedback Loop	Social Construction
Main assumptions	Processes can be described and designed in a rational way	Processes can be described and designed in a rational way	Magnitude of impact of policies on process performance is easily quantifiable through equations	Process change or process design can be negotiated in presence of conflicting interests
Consideration of dynamics	Static snapshot (of as-is or to-be situation)	Interaction between process components	Interaction between process structure and policies	Dynamics are considered implicitly as part of the subjective constructions of a business process
A process design is good if…	…the parts work *efficient*	…the process as a whole is *effective*	…the process is *effective* given a set of *policies* to be obeyed	…the perceived process exhibits "*cultural feasibility*"
BPM techniques	Flow charting and workflow modeling	Process simulation, quality management (statistical process control), business activity monitoring, and process mining	Process simulation and system dynamics modeling	Soft systems methodology
Related BPM activities	Process documentation, application development, certification, and benchmarking	"What if" analysis, discovery of previously unknown process behavior, and process control	"What if" analysis and gaining qualitative insight about process behavior	Learning about processes, engagement in unstructured process design problems, and management of "creative" business processes.
Main limitations	Lack of a time dimension Neglect of sociopolitical issues	Neglect of interaction between process structures and policies. Neglect of sociopolitical issues	Difficult to apply since the magnitude of impact of policies is hard to quantify Neglect of sociopolitical issues	Focus on "cultural feasibility" may impede radical process designs Not accessible to objective and quantitative assessment of process performance

the modeling of automated processes in the domain of workflow management, or for certification (e.g., quality management according to the ISO 9000 requires a documentation of business processes). Moreover, process models could be used to customize enterprise systems according to individual needs of an organization.

Process modeling is the main focus in the machine view, and research in this area increasingly focuses on the understandability and usability of particular modeling notations (see, e.g., zur Muehlen and Recker, 2008). Other research activities additionally study capabilities of modeling notations to map existing business realities onto a process model (e.g., see work on modeling grammars, as in Recker et al., 2011).

The main limitations of this deterministic machine view on a business processes are its assumption that business processes can be objectively perceived and modeled in a rational way (like engineering machines). It therefore neglects the sociopolitical dimension of BPM initiatives. Moreover, business processes as seen from a machine-view represent static snapshots of an as-is or a to-be situation and thus neglect the dynamic nature of processes, which are likely to change over time. However, as long as the main goal is to understand and clarify structural features of a process, then this view can still be useful.

26.3.2.2 Business Process as a Complex Dynamic System

In this view, a process can be understood as a system that dynamically adapts to a changing environment. From a systems perspective, a process has inputs, transformational capabilities, outputs, and a boundary to its environment. A process can also be hierarchically decomposed into subsystems (people, tasks, organizational structure, and technology) and elements (e.g., individual entities of each subsystem). Subsystems and elements interact with each other (internal relationships) and with the system's environment (external relationships) to achieve some superordinate objective (i.e., the system's objective). As opposed to the mechanistic perspective, this view emphasizes dynamic behavior of processes and interactions with an external environment (cf. Melão and Pidd, 2000). In particular, instead of analyzing the efficiency of its parts, this view encourages process managers to analyze process behavior holistically. Consequently, goodness of a process is more likely measured in terms of *effectiveness* (e.g., by employing quality and service level measures).

Besides the mechanistic view, this view on business processes as dynamic complex system is the predominant view today in both BPM research and practice. Many techniques and tools have been developed within the past decades to analyze and control complex process behavior. For example, TQM and techniques of *statistical process control* like *Six Sigma* have been developed and are applied under this particular view. Moreover, complex dynamic interactions within a process can be modeled and analyzed by means of *discrete-event simulation*. Many information systems (so-called process-aware information systems, cf. Dumas et al., 2005) keep track of user activities in so-called *event logs* enabling the analysis of process executions (PEs) through *business activity monitoring* (zur Muehlen and Shapiro, 2010) and also the discovery of "hidden" or formerly unknown process structures through *process mining* (van der Aalst, 2011). Furthermore, *execution semantics* of process modeling languages are defined in this view (see detailed discussion in this chapter on the business process modeling notation (BPMN) language in the subsequent sections). By means of such semantics, it can be analyzed if a given process model is "sound," that is, if it is able to be executed and if there is a danger of deadlocks in a process. Formalisms like Petri nets allow for mathematically proving process soundness. Many tools that support process modeling have a built-in functionality to animate the flow of flow units through a process and to automatically check process soundness.

In the past years, BPM research has widened its focus from solely analyzing process structures toward understanding interrelationships between process structures and other subsystems. For example, a research stream on value-oriented process modeling (see discussion in the subsequent sections and vom Brocke et al., 2010) explores the relations of process structures and the *value system* of an organization. Within this stream, important research contributions have been made with regard to goal-oriented process modeling linking the goal-systems of an organization with process

designs (e.g., Neiger et al., 2008). Goal-oriented process modeling can be applied to facilitate a strategic alignment of business processes with organizational goals or to support risk management activities in BPM. Another contribution in the value-oriented research stream has been made with regard to linking process modeling with the financial system of an organization (vom Brocke and Grob, 2011; vom Brocke et al., 2011) in order to analyze the impact of process design decisions on economic performance measures like the total cost of ownership, the return on investment (ROI), or the net present value (NPV).

While this complex dynamic systems view facilitates analyzing and understanding dynamic process behavior, it still shares critical assumptions with the mechanistic view. It still bears the risk to neglect the sociopolitical dimensions of a business process and it still implicitly assumes that process design and analysis can be approached in logical and rational terms (cf. Melão and Pidd, 2000).

Moreover, business processes as viewed from a complex dynamic systems perspective are assumed to have *no intrinsic control*, that is, the behavior of the system's elements is controlled by exogenous input variables and not by internal system states. In particular, policies that might "regulate" a system's behavior are not considered. Such systems are called *open loop systems*. Figure 26.3 illustrates an example of a complex dynamic system. The system under study is an airport, which might consist of subsystems like groups of passengers, IT resources, employees, and of course, a process system that determines the behavior of the "airport system." In particular, Figure 26.3 considers the process of "boarding a plane" from the perspective of the airport management. Airport management is interested in analyzing process performance in terms of passenger throughput, passenger queue length, or passenger waiting times (i.e., the relevant flow unit here are passengers). Since policies for conducting a passenger boarding are not considered, the process behavior at time t is determined by the arrival rates of passengers at time t (exogenous variable), the passenger queue length at time t, and the process structure (which in this case might be a sequence of a "check boarding pass" and a "complete boarding" activity). In the extreme event that all passengers arrive at the same time in front of the gate and are allowed to board the plane in the order they have queued (implicit first-in-first-out policy) process performance is likely to decline as time evolves since seat numbers among passengers are arbitrarily distributed. This might cause congestions within the airplane since passengers who have seats in the front of the plane temporarily block passengers seated in the back of the plane when trying to occupy a seat (anyone who has ever boarded a plane might have experienced such a situation). Figure 26.3 depicts the situation at three points in time. Initially, 150 passengers are waiting in front of the gate. After 3 min, 10 passengers have already found a seat while 20 passengers are waiting in front of an airplane. Additionally, 10 passengers arrive at the gate. After 10 min, already 50 passengers have found their seats. As is indicated in Figure 26.3, the number of passengers having found their seats in a particular row is randomly distributed and follows no particular pattern.

However, the existence of a policy, that is, the ability of the process to exert internal control over the arrival rate of passengers could lead to a better process performance since seats can be occupied according to particular patterns. An exemplary policy could be that "if the number of passengers in front of a gate G exceeds a threshold of x then only passengers in seat rows $[Y..Z]$ of a plane are allowed to board first." Such a policy would increase the probability that passengers find their seats more conveniently and thus congestion (see waiting queue in front of airplane after 10 min) could be avoided. This policy would interact with the first activity (e.g., "check boarding pass") and requires to model (information) feedback loops from "inside the airplane" activities to the boarding activity (so that the boarding activity is updated if boarding is complete for particular rows). The inability of an open loop systems view to account for the additional dynamics arising from internal system control (e.g., policies and information feedback loops) is the main limitation of this particular view. In fact, policies and feedback loops determine the behavior of many real-world processes (Melão and Pidd, 2000) and are thus worth to be considered properly. Remember that information structures have also been considered as an important aspect of the process concept in the preceding text (see Figure 26.1).

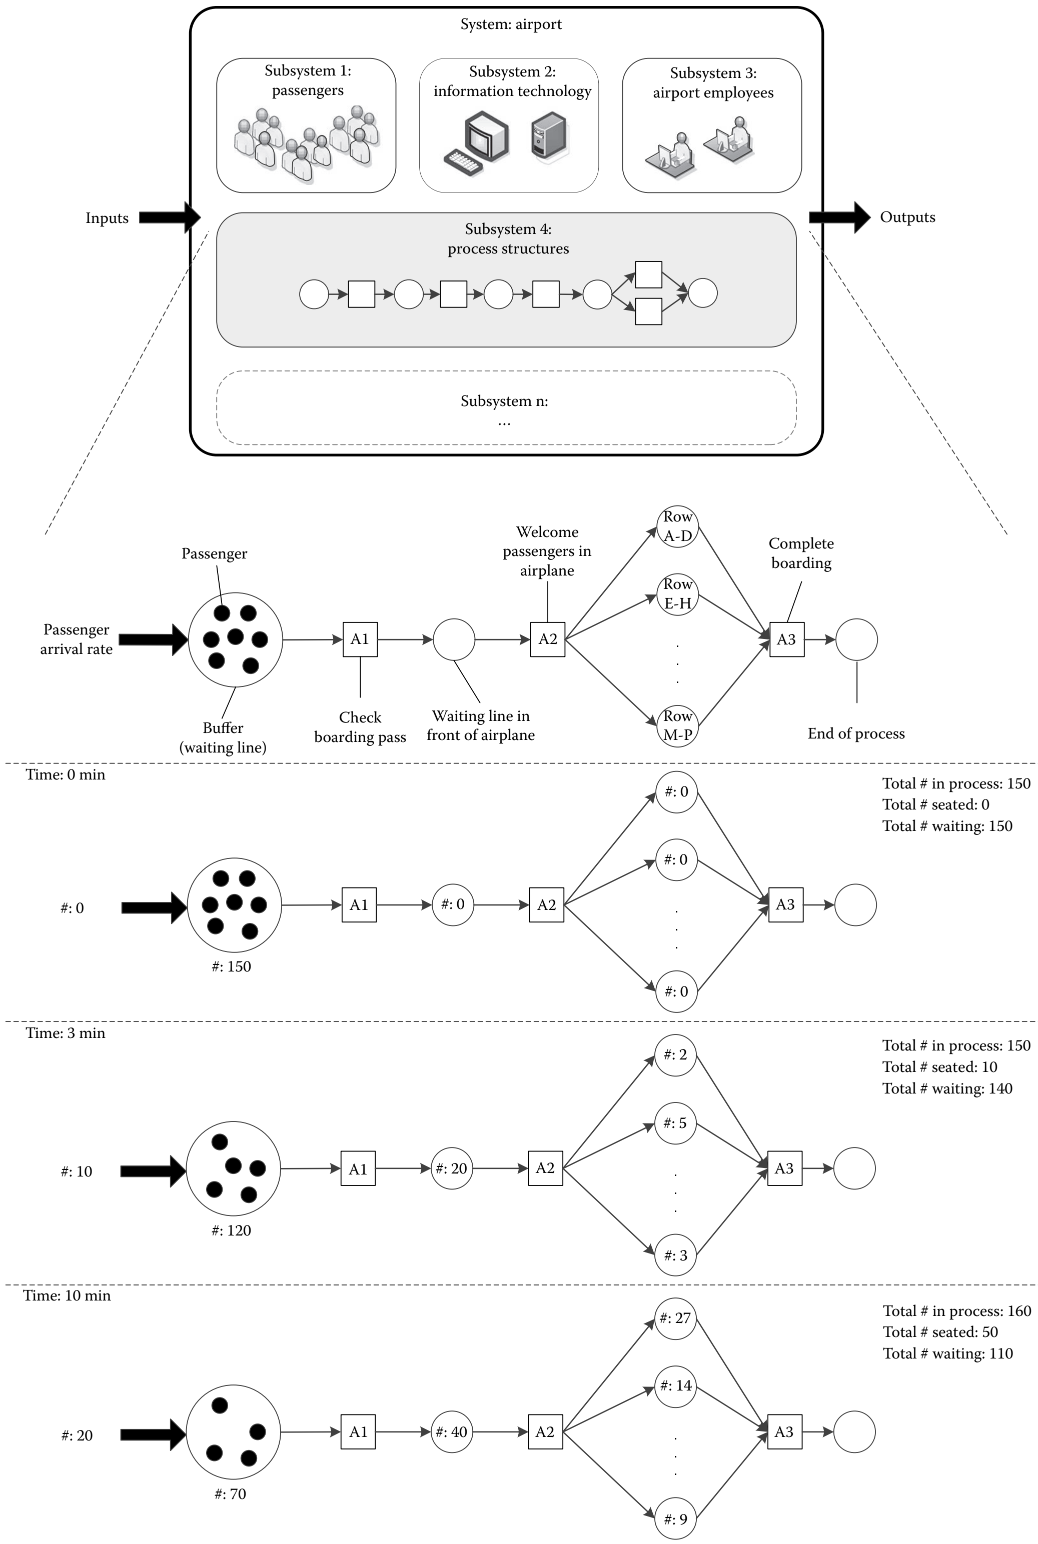

FIGURE 26.3 Exemplary process analysis in a complex dynamic systems view.

26.3.2.3 Business Process as an Interacting Feedback Loop

The view on business processes as interacting feedback loops is a refinement of the more general view on business processes as complex dynamic systems. The difference between these views lies in the nature of a system's control structure. Business processes in the feedback loop perspective can have internal control over their behavior and are thus characterized as *closed loop systems*. The main concepts used to represent processes as interacting feedback loops are *flows of resources*, *stocks* (for accumulating and transforming items), and *causal (feedback) loops*. The performance of a process is evaluated in terms of its *effectiveness* to achieve a set of process objectives given a set of *regulating policies*.

While this view is closely related to system dynamics modeling, it has been rarely applied within a BPM context (Melão and Pidd, 2000). Applications of this view could be useful in two ways: (1) as a means to *qualitatively* explore process structures by means of causal loop diagrams, and (2) in a *quantitative* way that translates the causal loop diagrams into equations, which then serve as a basis for process simulation.

The system dynamics view inherits some limitations of the more general view on business processes as complex dynamic systems. The human factor might only be considered in terms of an instrument to be controlled or exercising control (cf. Melão and Pidd, 2000). Moreover, system dynamics modeling might be difficult to apply since the "completeness" and "impact" of identified causal chains and feedback loops might be hard to prove and quantify. It is rather suggested to use system dynamics modeling in a "qualitative mode" to learn about process behavior.

26.3.2.4 Business Process as a Social Construction

This view on business processes does not assume that a process can be perceived and designed in a rational way but rather emphasizes that a business processes is an abstraction, meaning, or judgment as a result of a *subjective construction* and sense-making of the real world. Since the people that are affected by or are involved in a process have different values, expectations, and individual objectives, business processes are perceived differently by different stakeholders. Since these different perceptions can be conflicting, process changes have to be negotiated. Quality of a process is thus evaluated in terms of *cultural feasibility* (cf. Melão and Pidd, 2000).

In BPM practice, this view could be applied by means of the so-called soft systems methodology (SSM) (Checkland and Scholes, 1990). SSM employs systems thinking as a means to reason about people's perspectives on a business process. That is, a process description is used as a sense-making interpretative device to generate debate and learning about how a process is or should be carried out. A business process in SSM terms is thus a "would-be *purposeful human activity system* consisting of a set of logically interconnected activities through which actors convert inputs into some outputs for customers" (cf. Melão and Pidd, 2000, emphasis added). The human activity system is subject to environmental constraints and could be viewed from different angels depending on individual perceptions or social constructions of a process.

There are research reports demonstrating how to apply SSM in process change projects (e.g., Cahn and Choi, 1997; Galliers and Baker, 1995). However, research has yet to fully explore the potential of SSM in a BPM context, for example, with regard to linking SSM with more technical or "hard modeling" approaches (e.g., as supported by the complex dynamic systems or information feedback loop view).

Among sociopolitical elements, culture has been reported an important factor in BPM (Harmon, 2007; Spanyi, 2003), which has been further investigated in academic BPM studies (vom Brocke and Sinnl, 2011; vom Brocke and Schmiedel, 2011). BPM culture is defined as a set of organizational values supportive for realizing BPM objectives (vom Brocke and Sinnl, 2011). The so-called CERT values have been identified: (a) customer orientation, (b) excellence, (c) responsibility, and (d) teamwork; all four values have been found to be supportive for effective and efficient business processes (Schmiedel et al., 2013). The values are incorporated into a BPM culture model, and it is suggested that BPM initiatives are more likely to succeed if the specific organizational culture incorporates elements of the BPM culture model (vom Brocke and Sinnl, 2011).

A main limitation of this view on business processes is its sole reliance on *cultural feasibility*, which may impede more radical process designs and changes (cf. Melão and Pidd, 2000). Moreover, while this view is capable of capturing sociopolitical issues, it does not disclose how such issues could be dealt with. More recent research in BPM, however, does seem to overcome this limitation by designing tools for measuring, for example, the cultural fitness of an organization for BPM to very early identify barriers for process change and take preventive actions (like skill development and culture development) accordingly (Schmiedel et al., 2012).

26.3.3 Integrating the Multiple Perspectives on Business Processes

As can be seen from the aforementioned discussion, business processes can be viewed from several perspectives, which provide an account for the multifaceted nature of reality (cf. Melão and Pidd, 2000). While each of the discussed views has its limitations, they might well serve as a starting point for pluralistic approaches to BPM. For example, if a process under study is not well understood and bears potentially problematic implications for a group of people, then soft approaches can be used initially to gain consensus about what the process under study process looks like. A static approach as suggested by a mechanistic view on business processes can then be employed to document and communicate a process structure. In addition to such temporal combinations of the views, different process context can also call for specific process views to be predominantly applied. The mechanistic view on processes, for instance, is useful for analyzing and improving technical, well-defined processes, while the interacting feedback loop view or the social construction view might be more appropriate to study less structured business areas. Davenport (2005), for instance, discusses how the management of knowledge work can benefit from a process-oriented view. Also, the primary objective of process management can have an influence on the right view: If the analysis and improvement of process behavior is of interest, then the process analysis can be complemented by an approach that employs systems thinking. In particular, if (unpredictable) complex interactions within a process are not well understood, then approaches to disclose the process dynamics might prove to be useful, like process simulation, process mining, or business activity monitoring. Finally, if a business process is assumed to have feedback loops or some intrinsic control structures, then the systems view on processes should be extended to also consider the dynamics of policies.

Except for the social construction view on business processes, all views considerably assume that processes can be objectively perceived and process performance is rather independent of the people who participate within a process. Taken to an extreme, these views would suggest that processes can be optimized (even automatically) based on some quantifiable attributes. For complex and less technical processes, this assumption, however, has proven problematic already during the reengineering wave. Many re-engineering projects failed due to an overemphasis on designing technically sound processes at the cost of fostering social, cultural, and political resistance to change (Willcocks and Smith, 1995). Thus, a technically feasible and sophisticated process is a necessary but by no means a sufficient condition for the success of process change projects. Contemporary BPM therefore needs to follow a more holistic picture particularly integrating both technical and social elements of organizations as socio-technical systems (Bostrom and Heinen, 1977). BPM is, therefore, considered an integrated management discipline (Rosemann and vom Brocke, 2010) that seeks to build organizational capabilities to continuously improve and innovate business processes according to their very specific nature and given objectives and context factors.

For successful BPM initiatives, the problem, therefore, is not to favor a particular view on business processes. Instead, the contrary is the case. In order to capture the full richness and complexity of a situation, business process managers benefit from approaching the analysis and improvement of business processes in a multifaceted way (cf. Davenport and Perez-Guardo, 1999). Each view has its merits and limitations with regard to the analysis and improvement objectives to be achieved in a particular situation. Table 26.2 summarizes the different views on business processes as discussed earlier with its assumptions, limitations, and possible areas of application.

26.3.4 Process Analysis in the Context of a BPM Life Cycle

Having clarified the multifaceted nature of business processes, we now briefly discuss how BPM activities are affected by particular views and why process analysis is a significant task in an overall BPM initiative. Figure 26.4 depicts a BPM life cycle, which sketches the relationships between the activities to be conducted while managing business processes.

The BPM cycle starts with designing, documenting, and implementing a process. As opposed to the assumptions of the reengineering movement, process implementations do not always require the use of IT. For example, implementations of human-driven processes would require some simple procedures or policies to be obeyed by employees or other process participants. Once a process is up and running, a process manager might be interested in how the process performs with regard to some performance measures and with regard to the some competitors. Once a process performance gap is identified, corrective actions have to be planned in order to change the current process and transform it into a process with a more desirable performance. Once the process has been redesigned, it is again subject to performance measurement, and the cycle starts over again.

What can be seen from the description and from Figure 26.4 is that process analysis is a prerequisite to almost all BPM activities. Designing and documenting a process necessitates the initial analysis of existing process structures. Identifying performance gaps necessitates an analysis of the process behavior. Overcoming a performance gap and redesigning a process necessitates an understanding of the current process behavior and also an understanding of the to-be process as well as of the potentials to be unlocked by a new process design (cf. vom Brocke et al., 2009). Process analysis is thus central for gaining transparency about processes (in terms of structure and behavior).

In this regard, process modeling languages constitute an important methodological basis for BPM. Examples of such modeling languages are the event-driven process chain (EPC) or the UML activity diagrams. Selecting the "right" modeling language and the "right" view on a process in a given situation is becoming more and more difficult as BPM initiatives become more complex. This chapter provides a brief overview of some more widely used modeling languages and then introduces one specific modeling language that meanwhile has become an international industry standard: the BPMN. We employ a

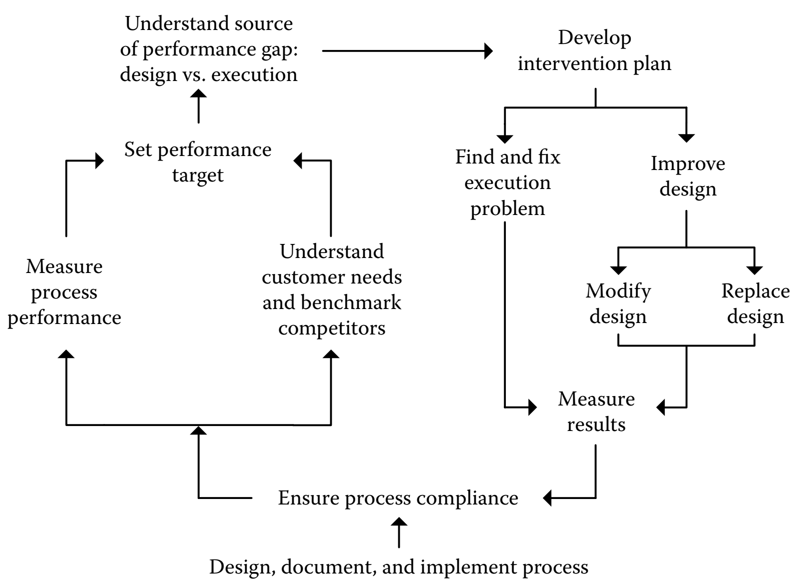

FIGURE 26.4 BPM life cycle. (From Hammer, M., What is business process management, In: *Handbook on Business Process Management*, Vol. 1, ed. vom Brocke, J. and Rosemann, M., p. 5, Springer, Berlin, Germany, 2010.)

complex dynamic systems view on business processes. We focus on the capturing of process structures under this view and the analysis of a particular kind of process behavior: *economic value creation*.

This particular type of behavior addresses an important question in BPM, which has so far received little attention. Process managers frequently have to choose a process (design) alternative (out of the large number of alternatives available in total) by judging which alternative appears to be the most beneficial one. Thus, this question is critical to the successful management of business processes. This chapter, therefore, particularly takes a look at this important dimension and presents methods that allow their users to compare and determine the economic value of different process reorganization alternatives. The methods for creating structural process transparency and process value transparency as presented in this chapter build upon each other in order to achieve maximum synergies between the modeling and the economic assessment of processes. Furthermore, the chapter demonstrates how useful financial key indicators, such as total cost of (process) ownership or ROI (of process redesign), can be calculated. Finally, the chapter presents a real-world example and briefly discusses its results.

26.4 Creating Transparency about Process Structures

26.4.1 Process Modeling Languages: A Brief Overview

In order to be able to create transparency about process structures, process modeling languages are used, which allow to describe the sequence of activities (in terms of time and logical order) within a process. As far as the development and use of such process modeling languages is concerned, a trade-off has to be made regarding the formalism to be employed. On one extreme, processes can be described in natural language (text-based modeling). On the other extreme, formal modeling languages can be used that restrict the use of the "modeling vocabulary" (modeling based on modeling grammars, cf. Recker et al., 2011). Natural language-based modeling languages are quite easy to understand. However, they are characterized by a large degree of freedom regarding the representation of process structures, which may be a reason not to use them for certain analyses as they might be too inexact. Formal modeling languages, on the other hand, do support such analyses, yet they are understood by relatively few experts only. The use of methods for process management therefore is closely connected with methods for semi-formal specification of business processes.

For example, the EPC (Keller et al., 1992) is a frequently applied process modeling language and is used for customizing the SAP® enterprise resource planning system. Nowadays, due to the considerable number of available modeling formalisms, process modeling languages are subject to standardization initiatives, for example, the UML (OMG-UML, 2011) or the BPMN (OMG-BPMN, 2011, as of Version 2.0 called business process modeling and notation). Especially the development of BPMN has been influenced a lot by some related and already widely used modeling languages (cf. OMG-BPMN, 2011, p. 1). Besides the EPC and UML activity diagrams, Integrated DEFinition for Process Description Capture Method (IDEF3; cf. Mayer et al., 1995) and ebXML Business Process Specification Schema (ebXML BPSS, cf. OASIS, 2006) have been considered throughout development of the BPMN. In addition, the BPMN execution semantics explicitly builds upon the formally defined semantics of Petri nets (Petri, 1962), which in turn is based on the concepts of "tokens" (see explanations further in the subsequent sections). Apart from BPMN, also EPC and UML activity diagrams each incorporate the Petri nets semantics.

The process modeling languages described in Table 26.3 address different *modeling purposes*. EPC and IDEF3 are primarily used for specifying the functional requirements of business processes, mainly for designing *organizational structures* (in order to be able to meet requirements regarding documentation, certification, benchmarking, or process-oriented reorganization) (cf. Becker et al., 2011). UML activity diagrams and Petri nets, on the other hand, are predominantly used for designing process-oriented *application systems*. Some Petri net variants are used for modeling *workflows* (i.e., processes of

TABLE 26.3 Overview of Process Modeling Languages

Modeling Language	Short Description
EPC (Keller et al., 1992)	EPC is a semi-formal modeling language for describing processes. EPC represents processes as *sequences of events and functions*. The EPC does not distinguish between start events, intermediate events, and end events. The architecture of integrated information systems (ARIS) (Scheer, 2000) uses EPCs for describing the *process/control view*, which integrates of the four other ARIS views (*organization, function, data,* and *output*). The EPC is particularly suited for specifying the functional requirements of business processes (i.e., the modeling of business processes from a business perspective).
IDEF3 (Mayer et al., 1995)	Similar to BPMN and EPC, IDEF3 was developed with the intention to be easily learned and used by practitioners. IDEF3 is domain neutral and primarily supports the documentation of *process knowledge* (Mayer et al., 1995). IDEF3 process models are predominantly used for *process analysis* aiming at process re-organization. IDEF3 supports two strategies of documentation (*process centered* and *object centered*), for which two *views* (*schematics*) are provided (*process schematics* and *object schematics*). An IDEF3 process description may comprise one or more process and object schematics.
UML activity diagrams (OMG-UML, 2011)	UML activity diagrams represent one a particular UML diagram type. They are used for describing the behavior of *application systems*. Activity diagrams illustrate the dynamic aspects of single use cases, showing start and end events but not intermediate events. Although activity diagrams just like BPMN 2.0 are based on *Petri net semantics*, the execution semantics of the two modeling languages differ widely with regard to certain aspects. For example, a process described by an activity diagram ends when at least one final node has been marked with a token (see the discussion on the token concept in the subsequent text). In contrast, a BPMN process remains active as long as there are any tokens in a process. When specifying the functional requirements of business processes, practitioners often combine activity diagrams with other UML diagram types in order to be able to separately illustrate functional requirements and technical requirements in a *use case diagram* or to describe relations between business relevant process object types in *class diagrams*.
Petri nets (Petri, 1962)	Petri nets come with a simple graphical process modeling language that can be used both for describing the behavior of application systems and for modeling business processes. Petri nets are based on a concept of *tokens, places* (i.e., *events*), and *transitions* (i.e., *functions/activities*). Petri nets do not allow the expression of different views of a business process. By means of the token concept, Petri nets provide an *instrument for abstraction* that allows to describe and *formally analyze the semantics of control flows*. A lot of the more recent modeling languages use Petri nets semantics, which allows analyzing processes with regard to cycles, deadlocks, or inaccessible paths.
BPEL (OASIS, 2007)	The OASIS is standard "business process execution language for web services (BPEL4WS or BPEL)" is an *XML-based, machine-readable* process description language. A BPEL process can be understood as a *web service* that interacts with other web services. BPEL can be used to describe both *inner-organizational and cross-organizational processes*. The BPMN defines *rules* for transforming graphical BPMN process models into BPEL models.
ebXML BPSS (OASIS, 2006)	The ebXML business process specification schema (BPSS) is an *XML standard* maintained by OASIS that allows describing processes in a textual, *machine-readable* way. ebXML-based process descriptions specify which business partners, roles, collaborations, choreographies, and documents are involved in the execution of a process. The focus is on describing *cross-organizational exchange of business documents*, i.e., the modeling of cross-organizational processes.

fine granularity) where transitions of activities are controlled by application systems (a *process engine*). Process descriptions used as input for such application systems are thus required to be machine readable. Such descriptions can be provided by non-graphical, XML-based process modeling languages (such as BPEL or ebXML BPSS), which allow to generate technical, machine-readable process descriptions that can be interpreted and executed by a process engine. The graphical representation of process models is not a primary aspect of these process modeling languages. However, there are a few languages that allow to seamlessly map graphical process descriptions onto technical, machine-readable process descriptions in order to close the gap between process modeling from a business perspective (functional requirements of a business process) and the actual PE. Sample notations that aim at linking a business perspective with a technical perspective on business processes are the BPMN (OMG-BPMN, 2011), the activity and sequence diagrams of the UML (OMG-UML, 2011), or yet another workflow language (ter Hofstede et al., 2010).

In recent years, BPMN has developed into an industry standard for process modeling. BPMN aims to provide a notation for graphical description of business processes that allows to consistently connect both *process design* and *process implementation* (cf. OMG-BPMN, 2011, p. 1). BPMN process descriptions are supposed to be understood by both technical developers and business analysts. Furthermore, the BPMN aims at adequately visualizing technical, XML-based process descriptions in order to be interpretable by human actors. In general, BPMN is supposed to facilitate the end-to-end modeling of processes, starting with process descriptions from a functional perspective, which are then more and more refined until a detailed BPMN model is developed from which a technical process description (e.g., in BPEL) can be generated.

Version 1.0 of BPMN was launched in 2004. It was developed by the Business Process Management Initiative Notation Working Group, which then was merged with the Object Management Group (OMG) in 2005. Since then the OMG has been responsible for maintaining the BPMN. In 2011, the OMG published Version 2.0 of the BPMN, following Version 1.2. Among the new features are two additional diagram types: conversation diagrams and choreography diagrams. As of Version 2.0, it is also possible to extend BPMN with own notation elements.

Taking into account certain element types that had already been part of earlier versions of BPMN, Version 2.0 was extended primarily with elements that focus very much on the modeling of executable process models. Thus, BPMN is focusing more on the *design of workflows*. While there are a large number of BPMN notational elements available, in practice only a relatively small number of elements are actually required and used for the modeling and design of business processes (the so-called BPMN core, cf. zur Muehlen and Recker, 2008). The following section presents a selection of these core elements and concepts of BPMN.

26.4.2 Business Process Modeling and Notation

The presentation of central concepts and elements of BPMN refers to literature covering the fundamentals of BPMN (Havey, 2005; OMG-BPMN, 2011; Weske, 2007). The concepts and elements to be presented in the following sections have been selected according to their significance for getting a basic understanding of BPMN models. After providing a short overview of the BPMN diagram types, one specific diagram type, the *Business Process Diagram* (BPD), together with its most important notational elements is presented in detail. Subsequently, one section is dedicated to the analysis of the behavior of BPMN process models by discussing the BPMN execution semantics.

26.4.2.1 BPMN Diagram Types

As has already been mentioned, the BPMN supports the modeling of sequences of activities (in terms of time and logical order). Prior to Version 2.0, the BPMN considered one diagram type only: the *BPD*. Unlike other process modeling languages (such as EPC or IDEF3), the BPMN did not provide separate views on process models (e.g., value chain view, organizational structures, or data view).

As of Version 2.0, however, the BPMN offers the possibility to model a "global view" of the sequence of interactions taking place between several collaboration partners (i.e., of inter-organizational processes). Therefore, the BPMN has been extended with two additional diagram types: *conversation diagrams*, which specify conversations taking place in an interaction scenario (who is involved, what messages are exchanged), and *choreography diagrams*, which specify the course of a conversation. Both diagram types establish an external, cross-organizational view on the interplay between collaboration partners. The details of affected internal processes of conversation participants are then specified in BPDs.

For multi-perspective process modeling, the BPD has to be extended with additional diagram types, which are not part of BPMN (such as UML class diagrams for specifying complex organizational and data structures). Because of the central role of the BPD, its most important elements are presented in the following section.

26.4.2.2 BPD: Core Elements

The notational elements associated with the BPD represent so-called object types used to describe business processes (cf. OMG-BPMN, 2011, p. 27 ff.). The BPMN makes a distinction between *flow objects*, *connecting objects*, *swimlanes*, *artifacts*, and *data objects* (see Figure 26.5). The BPMN comprises much more elements than shown in Figure 26.5. The elements presented here are considered to be core elements of BPMN and the ones that are most frequently used in BPMN-based process modeling projects (cf. zur Muehlen and Recker, 2008).

Flow objects are used to describe the sequence of activities (*tasks*). Basically, the BPMN distinguishes atomic activities and activities that can be refined into sub-processes. That way it is possible to describe hierarchical process structures. Besides the tasks, *events* and *gateways* represent central notational elements of the BPMN. Events can initiate a process (start events), occur as external events during PE, be generated internally as a result of the execution of a task (intermediate events), or terminate a process instance (end events). When events occur, a process engine (i.e., an application system that coordinates and monitors the execution of the process) saves process-related data. The more a process description focuses on the technical implementation of a process, the more important it is to actually model events. Process modeling from a functional perspective often focuses on start events and end events only, including events related to state changes of relevant process objects (e.g., sending or requesting messages, creating or modifying documents). Besides simple, un-typed events, the BPMN provides multiple event types, of which *message events* are frequently used in process modeling. *Gateways*, finally, represent a third core notational element. They are used to illustrate decision points within a process.

Flow objects can be related to each other by means of *connecting objects*. There are three types of connecting objects provided by the BPMN. *Sequence flows* connect tasks with each other and specify the order in which they are supposed to be executed. *Message flows* connect tasks contained in different pools (see Figure 26.6) in order to be able to model a communication channel for exchanging message objects. *Associations* are used to relate flow objects to artifacts in order to be able to integrate additional information into the process description (e.g., to add information about input and output conditions for single tasks).

Swimlanes enable the specification of responsibilities regarding the execution of tasks. In particular, swimlanes allow the description of basic organizational structures. The BPMN divides swimlanes into *pools* and *lanes*. Self-contained processes are modeled within pools. Lanes are used to group tasks according to responsibilities for their execution.

Artifacts are used to integrate context specific information into a process model. The most frequently used artifact type is *annotation*. As of BPMN Version 2.0, it is possible to integrate additional custom notational elements (i.e., which are not defined by the BPMN standard) as artifacts in order to be able to adapt the BPMN to individual process modeling requirements (cf. OMG-BPMN, 2011, p. 8). Artifacts can be connected with flow objects and sequence flows.

Data objects represent all information and documents used or produced within a process. Unlike the EPC, for example, the BPMN does not provide the possibility to represent descriptions of

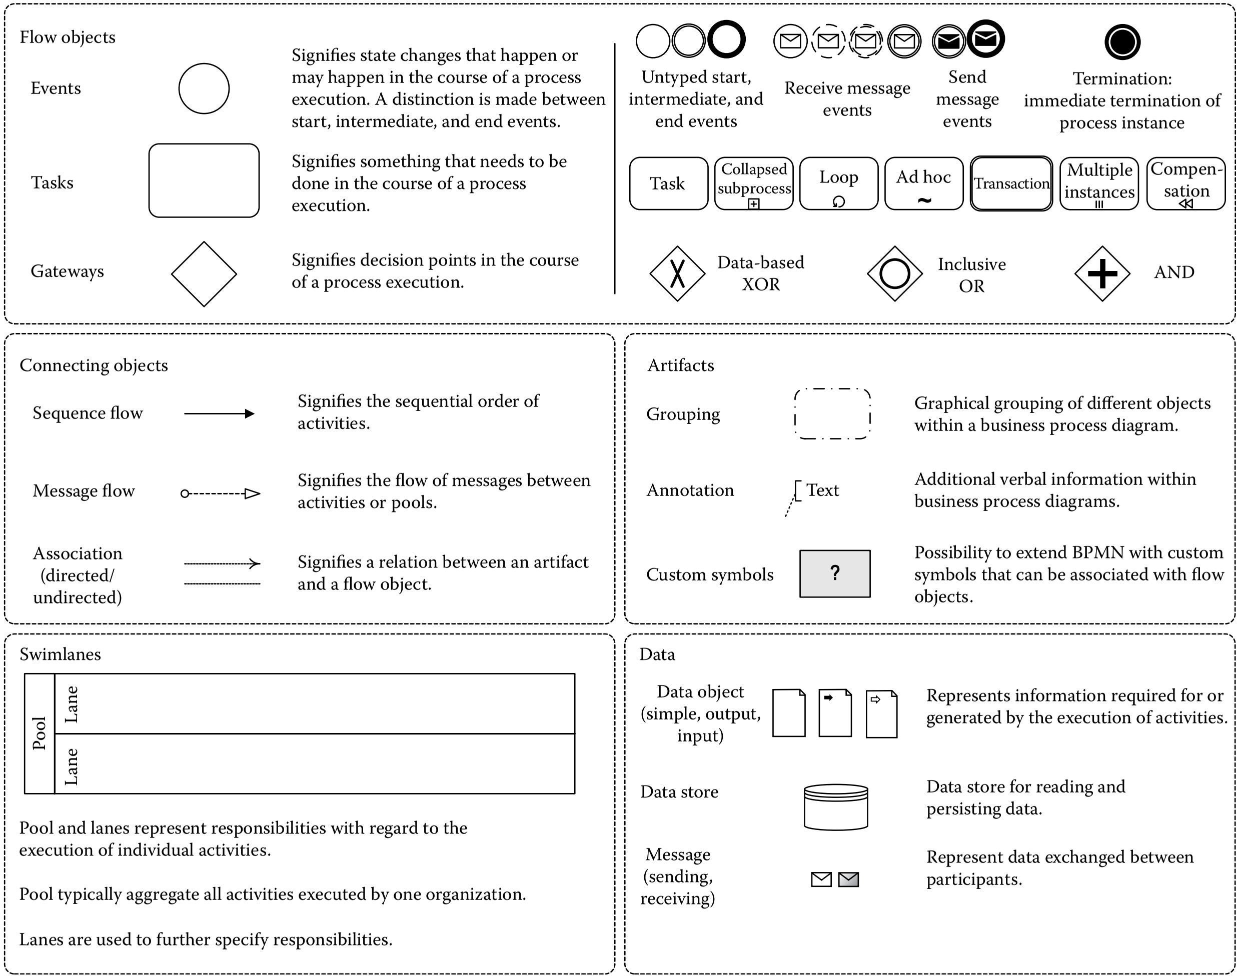

FIGURE 26.5 BPMN core elements. (From OMG-BPMN, Business process modeling notation (BPMN) information. http://www.omg.org/spec/BPMN/2.0/PDF (accessed March 7, 2011), p. 27 ff., 2011).

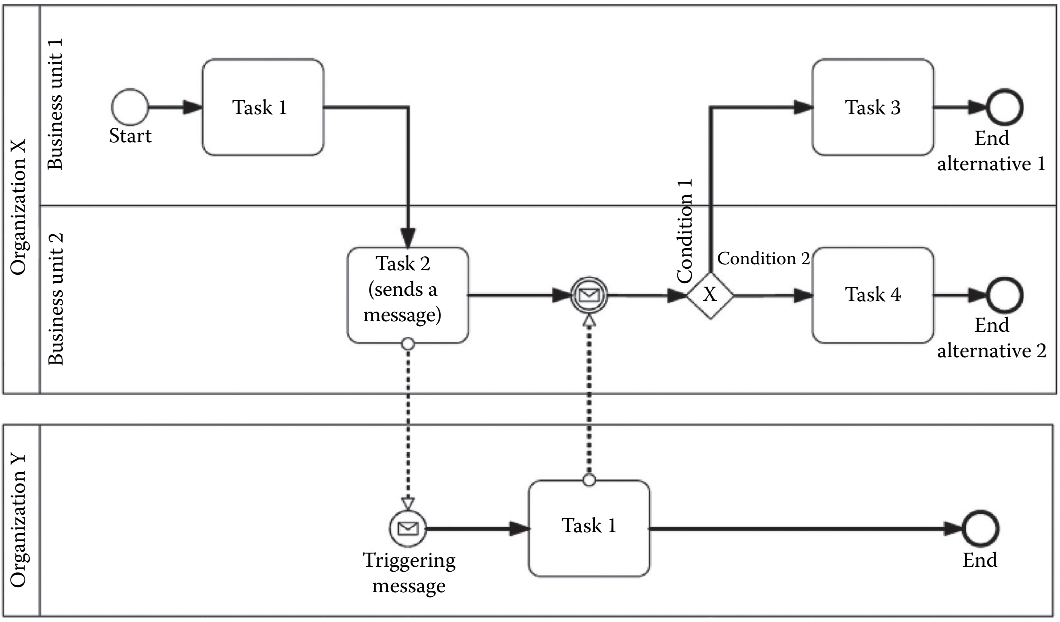

FIGURE 26.6 Example of a BPMN process model.

complex data structures within a process model or a separate view. Data objects are connected with flow objects via associations.

Figure 26.6 shows an example of an abstract BPMN process model. The graphic shows two internal processes (one for “Organization X” and one for “Organization Y”), each of which is embedded within a separate pool. The depicted situation typically applies in inter-organizational settings (such as, when a credit card check service is used prior to booking a flight). Processes contained in separate pools are connected with each other by message flows only (so-called choreography). In the example in Figure 26.6, such a choreography is initiated by the internal process of “Organization X.” After “Business Unit 1” has executed the first activity (Task 1), the process continues in “Business Unit 2” (Task 2), which sends a message to “Organization Y.” Upon receipt of this message, a process is triggered in “Organization Y.” Following an activity (Task 1) in “Organization Y,” a new message is generated and sent back to “Organization X.” Meanwhile, the process of “Organization X” waits until the message from “Organization Y” has been received. When the message has been received by “Organization X,” a gateway decides which one of two alternative activities is triggered and executed in “Organization X,” depending on predefined conditions (i.e., business rules).

26.4.2.3 BPMN Process Model Execution Semantics

The BPMN execution semantics specifies how a process behaves at the time of its execution (cf. OMG-BPMN, 2011, p. 425 ff.). A basic understanding of the execution semantics of BPMN process descriptions is useful to prevent process modelers from designing processes that do not behave as intended. Without considering execution semantics process models that are syntactically correct may still show unexpected behavior at runtime. For example, processes may be blocked (deadlocks), process paths could not be executed (inaccessible paths), or process areas repeatedly executed accidentally (cycles). Such malfunction of processes should be taken into account already during the phase of process modeling. For this reason, the BPMN 2.0 standard explicitly defines execution semantics of BPMN processes. These semantics have been derived from the Petri nets semantics and is based on the concept of *tokens*.

The token concept allows validating process structures in both the modeling phase as well as during PEs at runtime. Tokens are assumed to flow through a process instance along the control

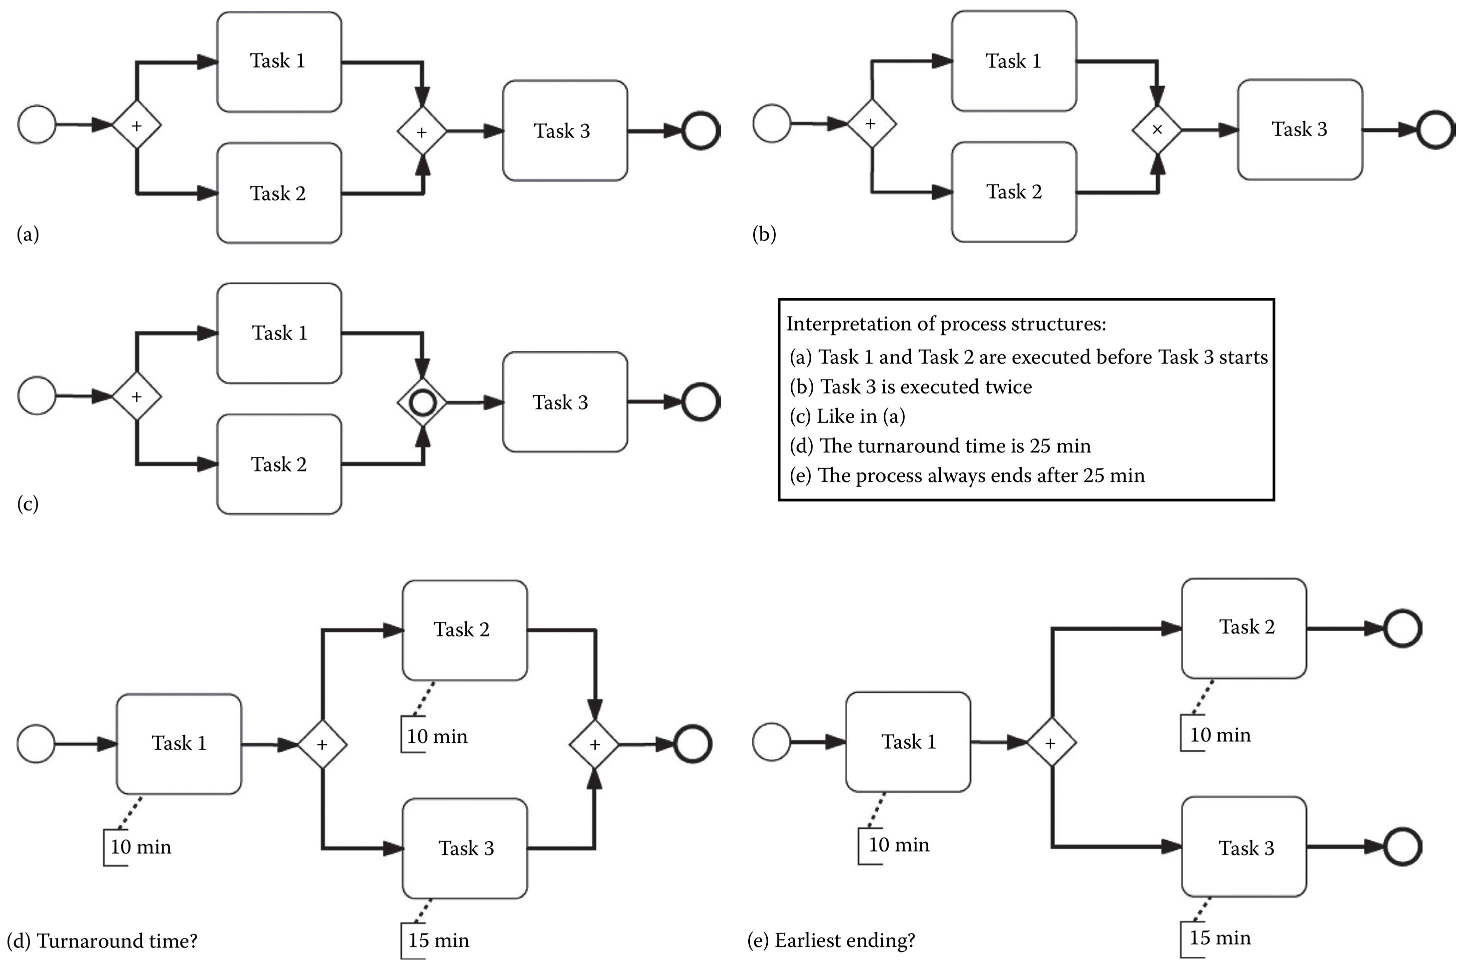

FIGURE 26.7 Examples of BPMN execution semantics. (a) Synchronization; (b) No Synchronization; (c) Synchronization (despite OR join); (d) Turnaround time?; (e) Earliest ending?

flow structures. In this sense, tokens can be interpreted as an abstraction of instances of single flow units that are expected to flow through a process (e.g., order "XYZ" that is processed). During PE, tokens can be multiplied, consumed, or created. As long as there is at least one token within a process instance, the associated process is considered being active. In order to validate the runtime behavior of a process, the token flow can be simulated. In the following, it is explained in detail how the token flow influences the execution of a process through a process engine.

Upon occurrence of a start event, a process engine creates a token with a unique identifier. This identifier signifies a particular process instance. If a start event is subsequently triggered, then a new process instance is created together with a new token and token identifier. Beginning at the start node, the token then starts to move forward through the process following the control flow specified by the process model. Tasks are executed only if they have been activated, that is, if a token has arrived on each incoming control flow edge and if each token refers to the same process instance. When a task is executed, all incoming tokens are consumed. If a task has been executed successfully, a new token is put on each outgoing control flow edge.

In case of XOR-nodes, a token is put on one and only one outgoing control flow edge. In case of AND-nodes (parallel execution), tokens are put on each outgoing control flow edge (tokens are cloned or multiplied). Unlike the EPC, for example, the BPMN does not provide specific rules or patterns as to how control flows are to be split and merged again. BPMN only provides rules specifying the behavior of mergers of control flows during PE. If a control flow is merged by an AND-node, subsequent tasks and events are not triggered and executed until tokens referring to the same process instance have arrived at all incoming edges of an AND-node. The control flow thereby gets *synchronized* (see Figure 26.7a), that is, one has to wait until all tasks of all incoming control flows have been successfully executed (see Figure 26.7d). If a parallel control flow is merged by a XOR-node (see Figure 26.7b), no synchronization takes place. As soon as one token has arrived at the XOR-node, it is passed on to activate subsequent tasks or events. If a control flow is split by an AND-node and merged by an outage risk (OR)-node (see Figure 26.7c), BPMN stipulates that the OR-merge behaves just like an AND-merge.

A BPMN process is active until all tokens of a process instance are consumed by an end node (i.e., there are no tokens left in the process any more, see Figure 26.7e). When a token has arrived at the "termination" node (see Figure 26.5), all tokens of a process instance are deleted instantaneously, and the process is immediately brought to an end.

After having discussed how process behavior can be analyzed in terms of process control flow structures and the flow of units within these structures, the next section aims at exploring how the economic consequences of a particular process design can be evaluated. This evaluation is still very often neglected in BPM practice due to a predominant focus on the technical implementation of specified process structures. Neglecting the analysis of economic impacts implied by a certain process design, however, may cause a technically sound process implementation to not deliver a satisfying process performance in terms of economic performance measures.

26.5 Creating Transparency about the Economic Value of a Process

26.5.1 Principles of Value-Oriented Process Modeling

The BPMN is a modeling language which is suited for modeling business processes from both a business-oriented and a technically oriented perspective. In doing so, BPMN basically facilitates the specification of structural and logical relations within a process. What BPMN does not take into account, however, are the economic consequences implied by a particular process design. This is tolerable as long as these consequences can be roughly overseen and are intuitively understood by decision makers.

However, assessing intuitively the economic consequences of design decisions made during the process modeling phase has become more and more difficult in recent years. Due to the sheer number of possible design options, it is hardly possible to reliably judge on an intuitive basis which process

alternative is superior to another and under what conditions this is the case. Because of that, it is important to explicitly analyze the economic consequences (i.e., economic value contribution) of design alternatives already at the time of process modeling (vom Brocke, 2007). In particular, decision makers are often interested in the financial performance resulting from the execution of business processes. When taking this aspect into consideration, it becomes obvious that transparency about process structures alone is not sufficient. What is needed in addition is transparency about the economic value created or consumed by a process. Thus, the process of business process modeling needs to be complemented by an accompanying process of calculating the value contribution of a process (vom Brocke, 2007) enabling a continuous and integrated assessment of the economic consequences pertinent to different business process alternatives (vom Brocke et al., 2009).

The analysis of economic consequences can be approached from different perspectives (cf. vom Brocke et al., 2010). A reasonable approach seems to consider economic value in terms of the degree of fulfillment of specific economic goals. The question to be answered is what economic goals are considered to be relevant in each individual case and how different goal dimensions need to be weighed. Stakeholder theory (as originally proposed by Freeman, 1984) provides a conceptual framework here to balance interests and goals of different groups that have a vested interest in a process or an organization. The problem of balancing different interests and assessing different goal dimensions properly has been reflected in various controlling (e.g., the balanced scorecard; cf. Kaplan and Norton, 1992). Process management frequently refers to different goal dimensions, such as cost, quality, and time (the magic triangle). More recent studies have extended this view beyond economic goals, integrating other goal dimensions in order to be able to assess also the ecological and social effects of the execution or reorganization of processes (Hailemariam and vom Brocke, 2010).

The present chapter aims to illustrate how economic consequences of process designs can be assessed by means of methods for capital budgeting. We chose to refer to this specific perspective since it is considered to be of particular importance in a capitalist economy. This perspective is also important since benefits of BPM initiatives are ultimately judged by means financial performance measures (cf. vom Brocke et al., 2010). Moreover, the approach to be presented may serve as a pattern for developing other assessment perspectives. A crucial prerequisite for the presented approach is the existence of process models. The overall goal of the approach is to overcome the methodological divide—that still exists both in theory and in practice—between process modeling and process controlling and evaluation in order to be able to improve both the efficiency and the quality of decisions taken in BPM and process controlling.

26.5.2 Constructs for Value-Oriented Process Modeling

In many practical cases, the question arises whether reorganizing a certain process pays off. Two aspects are decisive here: the benefits to be expected from a process reorganization and its price. Both aspects should always be assessed as early as possible in order to be able to ponder different design alternatives and make decisions that are as rational as possible. A lot of studies on process controlling (also often referred to as process monitoring or business activity monitoring) have proposed to use key performance indicators for controlling a process' value contribution at process run-time (for an overview on this see zur Muehlen and Shapiro, 2010). This proposal, however, is of limited use for assessing planned processes as opposed to evaluate running or finished processes. Studies have shown that the potential profitability of processes is significantly determined already during the phase of process modeling and less during the run-time phase of a process (cf. vom Brocke et al., 2010). What is remarkable though is that hardly any methods for such process evaluation during the phase of process design have been developed so far. Figure 26.8 shows a calculation scheme that can be applied to assess the economic value implied by a particular process design. This calculation scheme assumes that economic value is analyzed in monetary terms and follows a capital budgeting approach. The approach is explained in detail in the subsequent text.

The *benefit* of a process reorganization or a process (re-)design can be ascertained by comparing the *total payments of process ownership (TPPO)* for the case with reorganization (process p) and the case

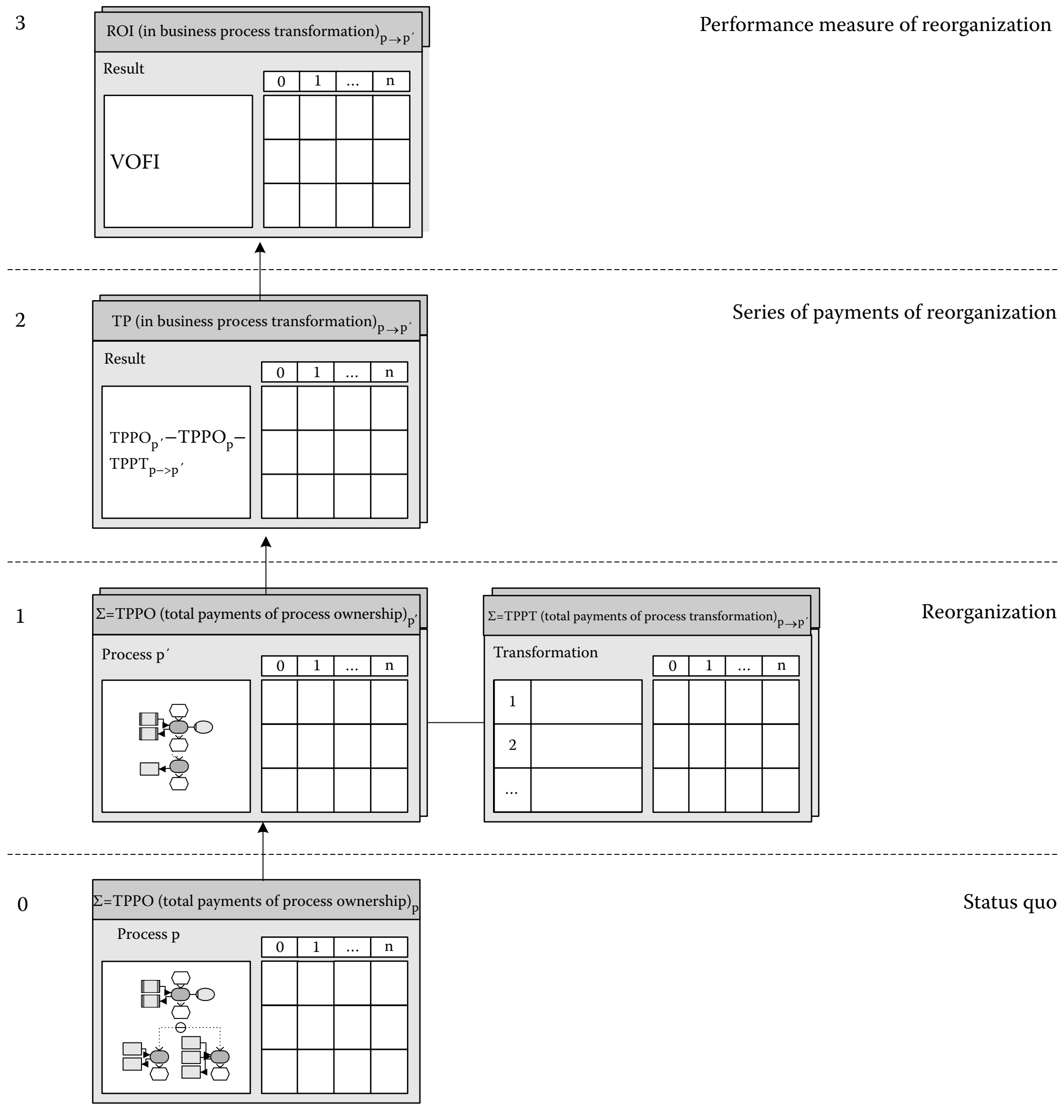

FIGURE 26.8 Calculation scheme (return on process transformation).

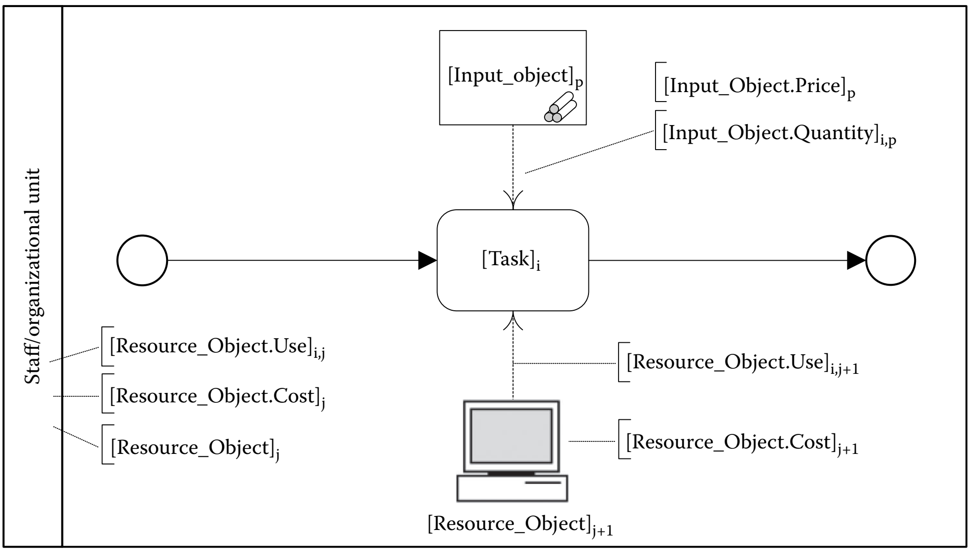
without reorganization (process p‘ = status quo) (level 1 and level 0 in Figure 26.8). The benefit resulting from a process reorganization is expressed by a positive difference between the $TPPO_{p‘}$ of the new process p‘ and the $TPPO_p$ of the same process at the status quo level (process p). The *price* of a process reorganization is the sum of the payments that need to be made for the transformation of the process (level 1). These payments are referred to as *total payments of process transformation (TPPT)* in the following. TPPT typically comprise payments for procurement of new IT, for the development of process knowledge, or for training employees affected by a (new) process design.

In order to be able to measure the TPPO and the TPPT, long-term economic consequences of the process reorganization need to be taken into account, which is why the planning horizon for the payments needs to span a substantial period of time (e.g., 5 years). By netting the series of payments ($TPPO_{p‘}$ – $TPPO_p$) and the investment in the process transformation (TPPT), the total expected payments resulting from the process reorganization can be calculated (level 2). This sequence of direct payments provides the basis for taking into accounting further financial consequences, including

indirect (derived) payments (such as interest and tax payments). To calculate the derived payments, various standard methods for investment controlling can be applied. Apart from applying classical methods for capital budgeting (such as the NPV or the internal rate of return), the method of visualization of financial implications (Grob, 1993) provides a suitable means to make the financial consequences of a particular investment transparent. It allows to make transparent how direct and indirect payments that are related by different financial conditions lead to a particular economic performance measure. This transparence has already proved to be very beneficial for process evaluation purposes (vom Brocke and Grob, 2011) as process design decisions could be directly related to expected payments and specific conditions of funding.

Assessing the TPPO on level 0 and on level 1 can be made at different degrees of detail. The financial planning approach allows both to specify in advance net payments to be expected for each planning period and to further differentiate the calculation of net payments without explicitly linking the payments to a particular process structure. Another interesting approach uses BPDs (see Section 26.3) as a basis for the assessment. To do so, BPDs must be complemented with information about economic consequences, as shown in Figure 26.9 with the BPMN.



Calculation formulae	Symbols
$[\textit{Out-payment.Input\_Object}]_i = \sum_{p=1}^{p} [\textit{Input\_Object.Quantity}]_{i,p} \cdot [\textit{Input\_Object.Price}]_p$	i Index for activities/tasks
$[\textit{Out-payment.Resource\_Object}]_i = \sum_{j=1}^{j} [\textit{Resource\_Object.Use}]_{i,j} \cdot [\textit{Resource\_Object.Cost}]_j$	p Index for input objects
$[\textit{Out-payment}]_i = [\textit{Outpayment.Iput\_Object}]_i + [\textit{Outpayment.Resource\_Object}]_i$	j Index for resource objects
	q Quantity of input objects
	m Quantity of resouce objects

FIGURE 26.10 Example template for determining the TPPT.

Figure 26.9 shows an example of how the payments of a process design alternative can be captured and consolidated through an *activity-oriented* approach. Out-payments are calculated based on the use or consumption of input objects and resources objects. All payments calculated for each activity (or task) can then be aggregated according to the process structure and extrapolated over several planning periods. This extrapolation of payments can be done either individually or by applying trend rates (cf. vom Brocke and Grob, 2011; vom Brocke et al., 2010).

To calculate the price (TPPT) of a process reorganization, certain calculation templates can be used for putting together typical payments with representational values for certain transformation tasks. It is important here as well to make an assessment that is as complete as possible, with due regard to both time and logical order. An example is given in Figure 26.10.

The approach for calculating the economic value in synch with process modeling, as presented earlier, is subsequently illustrated by means of a real-world example. The example has been taken from (vom Brocke et al., 2009) and used to demonstrate how transparency about both process structured and economic consequences implied by a process can be gained based on BPMN process descriptions.

26.6 Application Example

A medium-sized logistics company uses a web-based enterprise portal to support its business processes. The company management is thinking of conducting a process reorganization project with the aim to integrate the route planning process into its portal. In route planning, two kinds of planning types are distinguished: detailed planning and adhoc planning. In order to be able to determine the planning type for each delivery, order prioritization policies have been defined. Delivery orders of high priority are subject to detailed planning. If there is not enough time available for detailed planning, however, adhoc planning is applied instead. The problem with adhoc planning is that resulting routes may turn out to be inefficient as the delivery may not be made in time (leading to contractual penalties), and the truck fleet may not be deployed efficiently.

The fact that route planning has always been done manually by this company and that manual planning is a very time-consuming effort, has led to a drastic overrepresentation of adhoc route plans, also for delivery orders of high priority. By integrating the route planning process into the enterprise portal the company hopes to reduce errors, meet delivery schedules, and achieve better deployment of resources. The technical implementation of the solution is to be done on the basis of

a service-oriented architecture. Prior to the implementation, different design alternatives need to be assessed that particularly impact the effectiveness and efficiency of the planning process:

1. *GlobalRoutePlanning*: An IT solution by means of which route plans can be created over an online interface and saved to the company's database. Using the service requires specific information, such as delivery orders, truck fleet capacity, order prioritization, delivery addresses, and delivery dates. Using this solution, the process of route planning is fully "out-tasked."
2. *GeoDataForLogistics*: An in-house solution by means of which internal routing rules and customer data get enriched by external route information provided by a special geographic map service particularly suited to the needs of logistics companies. While this service is able to substantially reduce the planning effort, it also requires the development of a number of data services (wrappers) in-house.
3. *IntelligentRouting*: A web service by means of which fully fledged route plans can be created (similar to *GlobalRoutePlanning*, but only for a particular geographic region). As the geographical data of this service is very much up to date (providing information on construction sites or blocked roads, for example), the planning quality is very likely to be significantly improved by this solution.

The internal route planning process is represented by means of a BPMN process model (see Figure 26.11). In order to be able to depict process alternatives and specify the quantity structure, company-specific notational elements (BPMN artifacts) have been integrated (see explanation of symbols in Figure 26.11). Calculation of payments is basically done according to the scheme illustrated in Figure 26.9. Two resource object types are relevant here: organizational unit (here: dispatching/scheduling) and the services to be integrated. The quantity structure relevant to the calculation of the use of resources is specified within the BPD by means of tables (proprietary artifact).

The process design alternatives are considered implicitly in Figure 26.11. In order to be able to integrate the services into the process, various infrastructure requirements are needed (e.g., purchase and maintenance of an enterprise service bus (ESB), implementation of interfaces, and in-house developments). Deciding in favor or against a certain service in this specific example is expected to have a local impact only, as there are no structural or institutional interdependencies with other process elements.

The BPD illustrates the design alternatives as they were given in the concrete case. Selection of a *to-be* model here is made on the basis of a comparison of alternatives taking into account financial key indicators. This calculation is shown in Figure 26.12 and illustrated in more detail for the case of the *IntelligentRouting* web service.

As the impact of the design decisions is only local, the calculation of the differences between alternatives can be made by means of a partial analysis for determining the direct payments. When calculating the difference, it has to be determined what the expected *additional payments*—compared to the status quo level (*as-is*)—of each design alternative are (*to-be*).

Using the service for the route planning process promises both a higher number of detailed plans potentially possible and a better quality of realized detailed plans (*rDP*). It is expected that the processing time of the activity "Create detailed plan" is reduced from 10 to 5 min. It is also expected that the error ratio is reduced (from 20% to 3% in case of the *IntelligentRouting* web service). Taking into account an available capacity of 1,825 working hours per period, a number of *PEs* of 18,250, and an OR of the web service of 3%, direct cost savings of 22,356 € compared to the status quo level can be expected in period 1 (calculation is based on the assumption of an average advantage of 2.50 € for creating a detailed plan compared to creating an ad-hoc plan).

For the *IntelligentRouting* web service, a transaction-based pricing model is assumed, with an average calculation rate of 0.25 € per transaction. The payments per period to be calculated on a service level are to be calculated on the basis of the execution frequency expected for the task

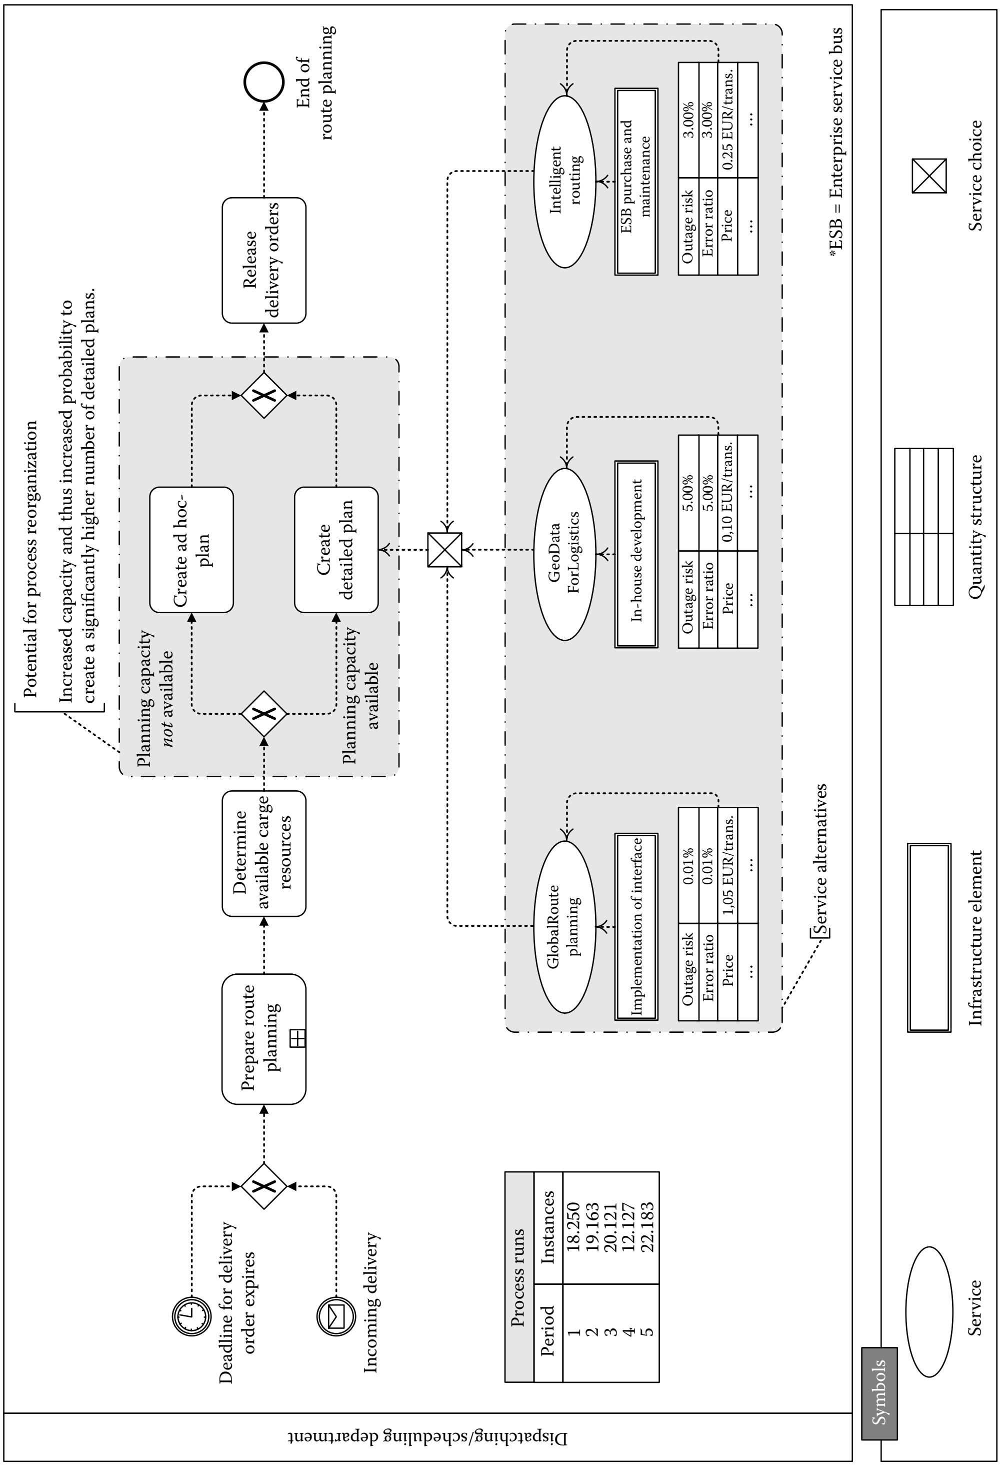

FIGURE 26.11 Business process diagram for process (route planning).

Direct payments

Period	0	1	2	...	5
− *IntelligentRouting*	−25.000 €	11.431 €	12.422 €	...	16.463 €

Formulae for evaluating the economic potentials

- $pDP_{as\text{-}is} = \dfrac{CA}{PT_{as\text{-}is}}$
- $mDP_{to\text{-}be} = \dfrac{CA}{PT_{to\text{-}be}} \cdot (1-OR)$
- $rDP_{as\text{-}is} = MIN\,(PE\,;\,pDP_{as\text{-}is}) \cdot (1-ER_{as\text{-}is})$
- $rDP_{to\text{-}be} = MIN\,(PE\,;\,pDP_{tp\text{-}be}) \cdot (1-ER_{to\text{-}be})$
- $\Delta rDP = rDP_{to\text{-}be} - rDP_{as\text{-}is}$

Symbols

- *CA* Capacity (hours/period)
- *PE* Process executions (#)
- *PT* Processing time (min)
- *ER* Error ratio (%)
- *OR* Outage risk (%)
- *pDP* Possible detail plans (#)
- *rDP* Realized detail plans (#)

FIGURE 26.12 Calculation of direct payments of the process reorganization.

"Create detailed plan" ($\approx rDP_{to\text{-}be}$). In period 1, for example, for 17,702 detailed plans created, the service payments amount to −4,426 €. If the route planning process is out-tasked, the calculation rate—at a lower OR—is 1.05 € per transaction, so that the expected payments rise accordingly (−19,161 €).

Apart from the activity-based payments ($TPPO_p$ and $TPPO_{p'}$), the payments for the process transformation (TPPT) also need to be taken into consideration. In this case, most of these payments primarily result from investments in the technical infrastructure. Using the *IntelligentRouting* web service requires the implementation of an ESB solution. In the case example, it is assumed that the company pursues an incremental implementation strategy. Therefore, a decision in favor of the *IntelligentRouting* web service brings about all payments for purchase of technical infrastructure (25,000 €) as well as all follow-up payments for maintenance and adaptation that occur periodically. In case *GlobalRoutePlanning* is used, with activities for detailed planning being out-tasked, payments for the technical infrastructure are substantially lower. If *GeoDataForLogistics* is used, more payments for the technical infrastructure are expected due to the relatively high implementation and development effort required.

With direct payments being consolidated by means of methods for capital budgeting, the future values of investing into the reorganization of the process are 30,379 € (*IntelligentRouting*), 25,424 € (*GlobalRoutePlanning*), and 26,235 € (*GeoDataForLogistics*). Compared to the future value of opportunity of 11,425 € (own equity compounded with an interest rate of 6 per cent), implementing any service can be considered beneficial to the company. The *IntelligentRouting* web service is the design alternative which generates the highest additional future value.

26.7 Conclusion and Outlook

This chapter aimed at providing an introduction into the basic concepts of BPM. It focused on phenomena pertinent to the task of business process analysis, as this task very central for BPM. While incrementally developing a multifaceted perspective on business processes and the task of business process analysis, this chapter particularly calls for integrating process modeling and process evaluation. We think the integration of process modeling with an economic analysis represents a meaningful contribution to the field of BPM. Current approaches for process modeling do not allow for assessing the economic value of process reorganization projects. Approaches for process evaluation or controlling (such as activity-based costing), on the other hand, have no differentiated understanding of process structures and take no advantage of process descriptions already available in practice.

As a consequence, we call for an integrated analysis of the structure of a process and its economic value contribution using an integrated set of methods and instruments. As both, established methods for process modeling (e.g., BPMN) and for capital budgeting are to be applied, the main challenge is to create interfaces between these two domains. How such interfaces can be realized on the basis of BPMN process descriptions has been one of the foci of this chapter. In particular, the chapter presented a procedure model to calculate th*e return on process transformation*, which integrates both a process structure perspective as well as a process value perspective.

Applying these methods in practice has shown that it is not always necessary to calculate at a high degree of detail. Using the set of methods presented in the article allows to simplify the evaluation procedures by starting to capture process structures in their entirety on a higher level of abstraction in order to be able to conduct a kind of "pre-assessment" first. Evaluations on a higher level may take into account only a few approximate values at the beginning, which can later be refined successively according to what is deemed necessary. Following this principle, one-day or two-day workshops often are a very good instrument for developing a basic understanding of which direction to go when thinking of reorganizing a certain business process.

More generally, we see the BPM discipline further establishing into a comprehensive management discipline. While contributions over the past decades were mainly focused on modeling, designing, and implementing selected processes of interest, BPM in the future will focus much more on developing capabilities inside organizations to continuously improve and innovate their business. With this,

the view of processes as social constructions in particular will play an increasingly important role. While the relevance of the social factor in BPM is often pointed at, little contributions are yet available to facilitate the management of processes as social constructions. Evaluating the financial performance of alternative process design is one approach to facilitate communicating process innovation and process transformation to different stakeholder groups, such as shareholders, in particular. Such approaches can help to strengthen capability areas such as strategic alignment and governance. Further areas or future research include people and culture as two distinct capability areas dedicated to the human factor in BPM.

Information Requirements Determination

Glenn J. Browne
Texas Tech University

27.1 Introduction

Information requirements determination (IRD) is the process of eliciting, representing, and verifying the functional and non functional needs for an information system (Browne and Ramesh 2002; Davis 1982; Hickey and Davis 2004; Larsen and Naumann 1992; Vitalari 1992). More broadly, IRD is a form of needs analysis, an activity required in any designed artifact, ranging from consumer products to software to industrial processes (Simon 1996).

The primary IRD process occurs early in the development of an information system, generally following the project planning process. IRD has traditionally been conceptualized within the traditional systems development life cycle (SDLC) (Kendall and Kendall 2010) as an early stage in the process. However, IRD is also utilized in its basic form in new approaches to systems development, including most “agile” development methods (Baskerville and Pries-Heje 2004; Lee and Xia 2010).

The importance of IRD to systems development is difficult to overstate. Because the IRD process occurs early in development and determines the needs for the system, all remaining activities in development, from modeling to design to coding to implementation, depend on specifying requirements that are as accurate and complete as possible. Elegantly designed systems that do not meet user requirements will not be used. Queries to databases that do not contain information users need will not be made. Thus, IRD is arguably the central activity in systems development.

Computer information systems serve a wide range of purposes in society. Regardless of whether the system is fully automated, such as a control system (e.g., a system operating temperature controls for a building) or a system that acts as a replacement for human decision makers (such as a loan application system), or is a system designed for interactive decision support (e.g., web-based shopping assistants), the requirements for the system must be determined by the systems analyst and developer. For this reason, requirements determination is also key to the computing profession generally.

27.2 Underlying Principles

The full information determination requirements process is often conceptualized as the development of a strategy for the elicitation of the requirements, their representation, and their verification (Larsen and Naumann 1992; Vitalari 1992). Development of a strategy was described well by Davis (1982), but little recent research has addressed the subject. Elicitation, or gathering or capturing of requirements, can be accomplished in at least four ways: asking, deriving from an existing system, synthesis from characteristics of the utilizing system, and discovering from experimentation from an evolving system (prototyping) (Davis 1982). Although all these sources are used at various times, this chapter will focus on the asking strategy, as it is the primary strategy utilized.

The asking strategy for elicitation is performed primarily through discussions with people who use or will use the system. Two other methods also important in elicitation include (1) examination of (a) internal documents such as organizational forms, reports, procedures manuals, policy documents, strategic plans, training materials, documents concerning existing systems (whether computerized or manual), and other company records and (b) external documents such as books, scholarly articles, white papers, and web-based materials and (2) observations of people performing tasks relevant to the system being developed. The focus of this chapter will be primarily on elicitation of requirements from users, but examining documents and observation will also be discussed briefly.

Representation of requirements is accomplished by analysts using informal models (such as flow charts, conceptual maps, knowledge maps, and cognitive maps) and semi-formal models (such as entity-relationship diagrams, data-flow diagrams, and Unified Modeling Language diagrams) (Browne and Ramesh 2002; Montazemi and Conrath 1986; Robertson and Robertson 2006). Verification is conducted by discussing the analyst's understanding of the requirements with the user, utilizing models, diagrams, written notes, and/or any other representational or verbal means available. Although the full process is critical to the systems development process, as noted, this chapter will focus on the elicitation of requirements from users.

Information system development can proceed in several different ways. The traditional SDLC model (usually termed the "waterfall" model or the "planned" model) is still used in a large majority of systems development efforts (Light 2009; Norton 2008) as it brings numerous significant advantages to the development process. However, the lack of quick user feedback on design efforts in the waterfall model has led to the creation of several alternative methods for systems development over the past 15 years or so. These methods are usually grouped together under the term "agile." Agile methods rely on short cycle times, small work modules, and rapid user feedback to improve system development outcomes (Baskerville and Pries-Heje 2004; Lee and Xia 2010). A set of basic requirements is needed even in agile methodologies, and so the discussion of IRD in this chapter is relevant to all methodologies. Nonetheless, there are differences in IRD between the two general approaches, and these differences are discussed in the *Impact on Practice* section.

27.2.1 Individual Level Principles

Asking users to specify information requirements relies on several fundamental cognitive and behavioral principles. Knowledge elicitation utilizes an interactive process in which the analyst stimulates the user to describe his needs in terms of inputs, processes, and outputs in the business process. Users are often encouraged not just to state "facts" but also to tell stories that reveal process activities that may otherwise remain unsaid (e.g., Alvarez 2002; Davidson 2002; Urquhart 2001). Stimulating users to evoke their knowledge requires that the analyst ask the right questions (Browne and Rogich 2001; Marakas and Elam 1998; Moody et al. 1998; Wetherbe 1991) to cause the user to access the correct "path" in memory. The more substantively knowledgeable (in the application domain) and procedurally knowledgeable (in systems development) the analyst, the more likely he will be to stimulate the user in appropriate ways. Failure to stimulate the correct path for the user can result in serious

(although unintentional) "misinformation" or lack of information elicited from the user and inaccurate requirements. Thus, the analyst's role in eliciting knowledge from users is usually both critical and challenging.

Analysts (and users) are limited in their information processing capabilities (Reisberg 2009; Simon 1996), and this constrains their ability to gather accurate and reasonably complete requirements (note that it can be persuasively argued that requirements are never "complete"). Perception is vastly limited; humans perceive a tiny fraction of information available in the environment at any point in time. Similarly, attention is also significantly limited. Most of what is perceived is not attended to and therefore does not enter working memory. Working memory is the mechanism through which everything we refer to as "thinking" takes place (e.g., reasoning, judgment, decision making, reflection, and introspection). Information in working memory that is elaborated upon and that has sufficient time to be stored ("consolidation") enters long-term memory. Working memory is severely constrained both by speed of processing (generally speaking, we are serial processors and can think about only one thing at a time) and capacity of processing (we are generally limited to four to nine pieces of information in working memory at one time, although the more complex the piece of information, the lower the number of pieces that can be considered). Long-term memory is also constrained. Because working memory processes so little information so slowly, most information to which we attend either does not enter long-term memory or enters only as fragments. We remember the "gist," or essence, of events but not the details (Brainerd and Reyna 1990). When asked to recall an event, a person must fill in the details of the event that were not stored. So, for example, when a user is asked by an analyst to recall an event that occurred, he will have to fill in the details (i.e., invent them) because he has no memory of those details. This can, of course, mislead the analyst. The other major problem with long-term memory is that people forget information. Nonetheless, it is generally believed that nothing is ever truly forgotten, and thus the goal for analysts is finding the right stimulus material to help the user locate the correct "path" to the memory (Reisberg 2009). This effort can be more or less successful.

Researchers have investigated numerous issues related to user and analyst cognition in IRD. As one example, recent research in requirements determination has investigated specific issues in long-term memory that affect the accuracy of requirements. Appan and Browne (2010) investigated a phenomenon referred to as "retrieval-induced forgetting." This psychological phenomenon shows that the act of recalling certain information (e.g., in response to a question from an analyst) causes related but currently unrecalled information to be suppressed in memory and therefore to be unavailable for subsequent recall from the same or similar stimulus. Thus, the first relevant information an analyst receives from a user concerning a particular issue is also likely to be the last; if the analyst returns to the issue in subsequent IRD sessions, he is likely to receive the same information from the user (Appan and Browne 2010; see also MacLeod 2002). This problem reduces the amount of information an analyst will learn about user needs and suggests the need to use multiple users at multiple points in time for IRD.
